## INTRODUCTION

## Study Area Description

The Tuolumne River is the largest of the three major tributaries (Tuolumne, Merced, and Stanislaus Rivers) to the San Joaquin River, originating in the central Sierra Nevada and flowing west between the Merced River to the south and the Stanislaus River to the north (Figure 1). The San Joaquin River itself flows north and joins the Sacramento River in the Sacramento-San Joaquin Delta within California's Central Valley. The Tuolumne River is dammed at several locations for generation of power, water supply, and flood control - the largest impoundment is Don Pedro Reservoir.

The lower Tuolumne River corridor extends from its confluence with the San Joaquin River to La Grange Dam at river mile (RM) 52.2.

The La Grange Dam site has been the upstream limit for

Figure 1. Location map of study area on the Tuolumne River. anadromous migration since 1871.

## Purpose and History of Study

Rotary screw traps have been operated at various locations in the Tuolumne River since 1995 within the winter/spring period to meet several objectives including monitoring the abundance and migration characteristics of juvenile salmonids and other fishes, and evaluation of reachspecific survival relative to environmental conditions (Table 1). The Turlock Irrigation District and Modesto Irrigation District (Districts) have supported all the RST program in 1995-97 and 2003-2008, and at the upstream sites in 1998-2000. Since 2006, sampling has also been conducted annually near the town of Waterford, about 25 miles upstream of the Grayson site, to provide comparative information in size, migration timing, and juvenile fall-run Chinook salmon production at a site downstream from most Chinook spawning activity, along with data on other fishes. An estimated 211 salmon (80 females) spawned in fall 2007.

## METHODS

## Juvenile Outmigrant Monitoring

## Sampling Gear and Trapping Site Locations

Rotary screw traps were installed and operated near Waterford and at Grayson River Ranch (Grayson). The traps, manufactured by E.G. Solutions in Eugene, Oregon, consist of a funnelshaped core suspended between two pontoons. Traps are positioned in the current so that water enters the 8 ft wide funnel mouth and strikes the internal screw core, causing the funnel to rotate.

As the funnel rotates, fish are trapped in pockets of water and forced rearward into a livebox, where they remain until they are processed by technicians.

The single Waterford trap was located at RM 29.8 approximately two miles downstream of the Hickman Bridge. The trap was held in place by a $3 / 8$-inch overhead cable strung between two large trees located on opposing banks. Cables fastened to the front of each pontoon were attached to the overhead cable. Warning signs, flashing safety lights, and buoys marked the location of the trap and cables for public safety. In 2008, two "wings" were attached at 45-degree angles to the outer edge of each pontoon near the upstream end of the trap (Figure 2). The "wings" consisted of $4 \mathrm{ft} x 4 \mathrm{ft}$ aluminum frames with removable plywood inserts. The "wings" were created to increase velocity at the trap, as well as improve catch efficiency.

Figure 2. Waterford rotary screw trap with "wings" attached to the upstream end of the pontoons.
At Grayson (RM 5.2), two traps were held in place by an overhead cable strung between two large trees located on opposing banks. Leader cables descended from the overhead cable and were attached to the front of each of four trap pontoons. The downstream force of the water on the traps kept the leader cables taut. In 2008, a structure similar to a weir was constructed and placed in the river approximately 50 ft upstream of the Grayson traps on the south bank in order to divert more water towards the traps and thereby increasing velocity at the traps (Figure 3).

The "weir" was constructed of three 4 ft x 8 ft sheets of plywood attached to t-posts that were set in the substrate at a slight angle to the flow.

Figure 3. Grayson rotary screw traps with "weir" structure approximately 50 feet upstream of the traps on the opposite bank.

## Trap Monitoring

Sampling at Waterford began on January 8. The trap was operated continuously ( 24 hours per day, 7 days per week) until June 2 when sampling was terminated due to low catch and inadequate depth and water velocity for trap operation. Rotary screw traps with $8-\mathrm{ft}$. diameter cones generally require water at least 4 feet deep and velocity of at least $1.5 \mathrm{ft} / \mathrm{s}$ for the cone to rotate.

Sampling at Grayson began on January 29 - an earlier onset was delayed due to continuing wet levee conditions that hampered access for installation by boom truck. Installation of the Grayson traps occurred when it was determined feasible to assemble them further upstream with suitable access followed by transport on the river to the sampling location. The traps were operated continuously ( 24 hours per day, 7 days per week) until sampling was terminated on June 4 due to low catch and inadequate depth and water velocity for trap operation.

Regardless of location, each trap was checked at least every morning throughout the sampling period, with additional trap checks conducted as conditions required. During each trap check, contents of the liveboxes were removed; all fish were identified and counted; and any marked fish were noted. In addition, random samples of up to 50 salmon and 20 of each non-salmon species during each morning check and up to 20 salmon and 10 of each non-salmon species during each evening check were anesthetized, measured (forklengths in millimeters), and recorded. Salmon were assigned to lifestage category based on a forklength scale, where <50 $\mathrm{mm}=$ fry, $50-69 \mathrm{~mm}=$ parr, and $\geq 70 \mathrm{~mm}=$ smolt. In addition, the smolting appearance of all measured salmon and trout was rated based on a scale, where $1=$ yolk-sac fry, $2=$ fry, $3=$ parr, $4=$ silvery parr, 5= smolt, 6= mature adult, and IAD= immature adult (Interagency Ecological Program unpublished). Weights were taken from up to 50 salmon each week (i.e., Monday through Sunday) and from all trout. A weight boat partially filled with stream water was placed on an Ohaus digital balance and the balance was tared. One fish was placed in the weigh boat and after the weight was recorded to the nearest tenth of a gram, the balance was tared again before adding the next fish. Several fish were weighed before the weigh boat was emptied into a recovery bucket.

Salmon daily catch was equivalent to the number of salmon captured during a morning trap check plus the number of salmon captured during any trap check(s) that occurred within the period after the previous morning check. For example, the daily salmon catch for April 10 is the sum of salmon from the morning trap check on April 10 and the evening trap check conducted on April 9. Separate daily catch data was maintained for marked and unmarked salmon.

After all fish were measured and recorded, the traps were cleaned to prevent accumulation of debris that might impair trap rotation or cause fish mortality within the liveboxes. Trap cleaning included removal of debris from all trap surfaces and from within the liveboxes. The amount of debris load in the liveboxes was estimated and recorded whenever traps were checked.

## Trap Efficiency Releases

Trap efficiency tests using natural or hatchery juvenile salmon were conducted to estimate the proportion of migrating juvenile salmon sampled by the Waterford and Grayson traps. Natural salmon captured in the traps were used to conduct tests whenever catches were sufficient to obtain a group of at least 30 fish over no more than two days. Due to low catches of natural salmon at the Grayson traps, only one natural release group was used and remaining tests were performed using hatchery fish. Conversely, no hatchery fish were released for Waterford trap efficiency tests.

For trap efficiency estimates at Waterford, nine groups of fish (all natural release groups ranging in number from 32 to 140 marked fish) were released at RM 30 (about 0.2 miles upstream of the trap) between January 13 and May 16. All marked fish were released after dark.

For trap efficiency estimates at Grayson, six groups of fish (one natural and five hatchery groups ranging in number from 73 to 1,131 marked fish) were released at RM 6.2 (about 1 mile upstream of the traps) between March 1 and May 21. All marked fish were released after dark.

## Holding Facility and Transport Method

Natural fish were transferred from liveboxes into either 5-gallon buckets or 20-gallon insulated coolers depending on the number of fish, temperatures, and distance traveled and transported by boat upstream to the release site.

Hatchery fish for trap efficiency releases were transported from the Merced River Hatchery (MRH) to the release site on the Tuolumne River by the California Department of Fish and Game (CDFG).

At release sites, fish were held in live cars constructed of 15 " diameter PVC pipe cut into 34 " length (Figure 4). A rectangle approximately 6 " wide by 23 " long was cut longitudinally along the pipe and fitted with aluminum or stainless mesh. Live cars were tethered to vegetation or other structures and kept in areas of low water velocity to reduce fish stress.

Figure 4. Live car used for holding trap efficiency test fish.

## Marking Procedure

At both trapping sites, natural fish were marked on shore immediately adjacent to the trap and were then transported to the release site where they were held until release. Hatchery fish were marked at the Merced River Hatchery and then transported to the release site approximately 8-12 hours before the release. A photonic marking system was used for marking all of the release groups because of the high quality of marks and the ability to use the marking equipment in rapid succession. All fish were anesthetized with Tricaine-S before the appropriate mark was applied. With this method, a marker tip was placed against the caudal fin and orange photonic dye was
injected into the fin rays. The photonic dye was chosen because of its known ability to provide a highly visible, long-lasting mark. The photonic dyes were purchased from Day-Glo, Cleveland, OH.

## Pre-release Sampling

Prior to release, marked fish were sampled for mean length and mark retention. Fifty fish (or the entire release group if fewer than 50 fish) were randomly selected from each release group, anesthetized, and examined for marks; and the remaining fish in each group were enumerated. Mark retention was rated as present or absent. A total of four fish were found to have no marks upon examination and were removed from the release groups. All fish released in 2008 had visible marks.

## Release Procedure

Livecars were located several feet away from the specific release point and fish were poured from the live cars into buckets for release. Fish were released by placing a dip net into the bucket, scooping up a "net-full" of fish, and then emptying the fish into the river so they could swim away. After releasing a "net-full" of fish, about 30 seconds to 3 minutes elapsed before another group of about a "net-full" of fish was released. Amount of time between "net-full" releases varied depending on how fast fish swam away after their release. Total release time for marked groups ranged from six minutes to 70 minutes depending on the size of the group.

## Monitoring Environmental Factors

## Flow Measurements and Trap Speed

Provisional daily average flow for the Tuolumne River at La Grange was obtained from USGS at http://waterdata.usgs.gov/ca/nwis/dv/?site_no=11265000\&agency_cd=USGS. Provisional daily average flow for the Tuolumne River at Modesto was obtained from the USGS at http://waterdata.usgs.gov/ca/nwis/dv/?site_no=11290000\&agency_cd=USGS. The Modesto flow station is below Dry Creek, the largest seasonal tributary entering the river downstream of La Grange Dam. As a result, that site includes flow associated with major winter runoff events. Velocity of water entering the traps was measured using two methods. First, the water velocity entering the traps was measured daily with a Global Flow Probe, manufactured by Global Water (Fair Oaks, CA). Second, an average daily trap rotation speed was calculated for each trap by recording the time (in seconds) for three continuous revolutions of the cone both before and after the morning trap cleaning, then averaging the two times per revolution recorded.

## River Temperature, Relative Turbidity and Dissolved Oxygen

Instantaneous water temperature was measured daily with a mercury thermometer at the trap site. Data was also available from hourly recording thermographs maintained by the Districts at Shiloh Road (RM 3.4) near the Grayson traps and by California Department of Fish and Game at Hickman Bridge (RM 32) near the Waterford trap. To measure daily instantaneous turbidity, a
water sample was collected each morning and later tested at the field station with a LaMotte turbidity meter, model 2020e. Turbidity was recorded in nephelometric turbidity units (NTU). Instantaneous dissolved oxygen was measured during trap checks with an Exstick II D600 Dissolved Oxygen Meter at the trapping sites and recorded in $\mathrm{mg} / \mathrm{L}$.

## Estimating Trap Efficiency and Chinook Abundance

The estimated daily number of fish passing each site was generated by either expanding the catch data by the average estimated trap efficiency for the lifestage captured (Waterford) or by a trap efficiency predictor equation (Grayson).

At Waterford, the trap efficiency dataset is limited because sampling has only been conducted during 2006-2008, and the dataset is not yet sufficient to develop meaningful regression relationships between trap efficiency and predictor variables such as river flow, fish size, or turbidity. In the interim, an estimate of salmon relative abundance for the sampling season was calculated by expanding the daily number of fish by the average observed trap efficiency for each lifestage during 2008, or $14.2 \%$ ( 97 recoveries from 685 released) for fry and $12.2 \%$ (5 recoveries from 41 released) for parr/smolts.

At Grayson, flow and trap efficiency data collected from 1999 through 2008 were used to develop a multiple regression equation to estimate daily trap efficiencies. Specifically, average daily river flow at Modesto, average fish size at release, and transformed (e.g., natural log) proportions of fish recovered from each release event were used to develop the following trap efficiency predictor equation with an adjusted $\mathrm{R}^{2}$ of 0.64 :

Daily Predicted Trap Efficiency=EXP(-0.29176+(-0.00042*Flow at MOD) $+(-0.03410 *$ Fish size))

Where Flow at MOD= daily average river flow at Modesto
Fish Size= daily average forklength of fish captured at Grayson
These daily predicted trap efficiencies (DPTE) were then applied to the daily catch (DC) to estimate daily passage as follows:

## Estimated Daily Passage= DC/DPTE

Rough estimates of daily passage were also calculated using the proportion of flow sampled by the trap(s) as a surrogate for trap efficiency. The proportion of flow sampled at each site was estimated by the following equation:

$$
N_{c}=C_{d} \sqrt{\frac{V_{d}\left(3.14 * \frac{r^{2}}{2}\right)}{F_{u}}}
$$

where, $\mathrm{N}_{\mathrm{e}}$ is the expanded daily number of fish; $\mathrm{C}_{\mathrm{d}}$ is the daily catch; $\mathrm{V}_{\mathrm{d}}$ is the daily velocity, r is the radius of the trap; and $F_{d}$ is the daily flow measured at La Grange plus flow from the Hickman spill.

## RESULTS AND DISCUSSION

## Chinook Salmon

## Number of Unmarked Chinook Salmon Captured

Juvenile salmon outmigration in the San Joaquin Basin typically occurs during the winter and spring, extending from January through May. The winter migration period is dominated by fry migrants that are typically less than 50 mm forklength, and the spring period is dominated by smolts which are typically greater than 70 mm forklength. During 2008, daily catches of juvenile salmon at Waterford were highest from late-January through late-February, and daily catches through mid-March primarily consisted of fry ( $<50 \mathrm{~mm}$ ) (Figure 5). Daily catches of juvenile salmon at Waterford between January 8 and June 2 ranged from zero to 236 fish and totaled 3,350 fish (Figure 5).

At Grayson, catches of juvenile salmon were highest during the month of February, and daily catches through early March primarily consisted of fry ( $<50 \mathrm{~mm}$ )(Figure 6). Daily catches of juvenile salmon at Grayson between January 29 and June 4 ranged from zero to 73 fish and totaled 193 fish (Figure 6).

Total annual catch of juvenile salmon has varied substantially between years at Grayson/Shiloh (Table 1; Figure 7). This variation is likely due to differences in one or more factors including the duration and timing of the sampling periods, flow conditions, and overall fish abundance (Table 1; Figure 7). Sampling periods have varied between years with sampling initiated as early as January or as late as April and continuing through May/June.

During 1999-2002, 2006 and 2008 sampling at Grayson encompassed the majority of the expected winter/spring outmigration season (i.e., January-May/June) and can be described as comprehensive (Table 1; Figure 7). In contrast, sampling was only conducted during the spring smolt outmigration period (i.e., April-May/June) in 1995-1997 at Shiloh and 2003-2005 and 2007 at Grayson, so sampling was incomplete for those years. Sampling during 1998 began in February but was limited to a single trap (note: two traps were operated in all other years); thus, 1998 sampling covered an intermediate proportion of the entire outmigration period relative to all other years of monitoring.

Of the winter/spring sampling years, total trap catch at Grayson ranged from a high of 19,327 during 1999 to a low of 436 during 2002, and averaged 5,040 juvenile salmon (Figure 7). In all years of spring-only sampling, catches ranged from a high of 1,239 during 2001 to a low of 27 during 2007. The proportion of the typical outmigration period monitored each year ranged from $81.5 \%$ to $97 \%$ during winter/spring sampling years, from $24 \%$ to $45 \%$ during spring-only sampling years, and was $70 \%$ in the intermediate sampling year (Table 1). These proportions
were calculated by taking the total number of sampling days in a given year and dividing by the total number of days for a typical complete outmigration period (i.e., January 1 through May 31). The proportion of the outmigration period sampled may not be representative of the proportion of the juvenile population migrating during the sample period because migration timing can be influenced by environmental factors such as flow.

Figure 5. Daily catch of unmarked Chinook salmon at Waterford and river flow at La Grange (LGN) during 2008.

Figure 6. Daily catch of unmarked Chinook salmon at Grayson and river flow at Modesto (MOD) during 2008.

Figure 7. Total annual salmon catch at Shiloh/Grayson during 1995-2008.

## Trap Efficiency and Estimated Chinook Salmon Abundance

In 2008, eight trap efficiency estimates for natural fry at Waterford ranged from 9.2\% to 34.4\% at flows (La Grange) ranging between 167 cfs and 173 cfs (Table 2; Figure 8). One trap efficiency estimate for natural, smolt sized fish at Waterford in 2008 was $12.2 \%$ at a flow of 811 cfs (Table 2). Average forklength at release of the nine trap efficiency test groups in 2008 ranged from 36 mm to 88 mm (Table 2).

At Grayson, observed trap efficiency estimates from 1999-2008 ranged from zero to $21.2 \%$ at flows (Modesto) ranging between 280 cfs and 7,942 cfs (Table 3; Figure 9). One trap efficiency estimate for natural fry at Grayson in 2008 was $6.9 \%$ at a flow of 342 cfs (Table 3). In 2008, five trap efficiency estimates for hatchery, smolt sized fish at Grayson ranged from $1.5 \%$ to $9.6 \%$ at flows ranging between 300 cfs and 1,310 cfs (Table 3). Average forklength at release of the six trap efficiency test groups in 2008 ranged from 38 mm to 96 mm (Table 3).

Daily predicted trap efficiency, and daily estimated passage at Waterford and Grayson in 2008 are provided in Appendices A and B, respectively.

Table 2. Trap efficiency results from Waterford during 2008.

Figure 8. Trap efficiency estimates at Waterford relative to river flow at La Grange (LGN) during 2008.

Figure 9. Trap efficiency observations at Grayson relative to river flow at Modesto (MOD), 1999-2008.

Based on calculated daily passage estimates, an estimated 24,894 unmarked Chinook salmon passed Waterford during 2008 and $34.3 \%$ of these were smolts. Relative to the estimated escapement of 211 spawners (Blakeman 2008) approximately 311 juveniles were produced per female spawner (Table 4). In comparison, $51 \%$ of the total number of unmarked fish that passed Waterford during 2007 were smolts and approximately 206 juveniles were produced per female spawner. In 2006, sampling efforts were affected by high spring flows resulting in passage estimates that were likely underestimated-particularly for smolts-so no comparisons between 2006 and other years were made. Similar to the pattern observed for catch, it is estimated that a majority of the salmon passing Waterford in 2008 prior to mid-March were fry and catch was then dominated by smolts from late-March through May (Table 4; Figure 10). Daily estimated passage at Waterford ranged from zero to 1,667 salmon. Peaks in daily passage for fry occurred on January 25 and smolt passage peaked on May 16 (Figure 10; Figure 11).

An estimated 3,283 unmarked Chinook salmon passed Grayson during 2008 and $71.6 \%$ of these were smolts (Table 4). Daily estimated passage at Grayson ranged from 0 to 445 salmon. Peak daily passage for fry occurred on February 29 and smolt passage peaked on April 27 (Figure 12). During comparable seasonal sampling in previous years at Grayson (i.e., winter/spring sampling in 1999-2002, 2006, and 2008), total estimated passage ranged from a high of 696,115 in 1999 to a low of 3,283 in 2008 (Table 1; Figure 13) and the proportion of passage as smolts was the highest in 2002 (94.5\%) and the lowest in 1999 (4\%). In spring-only sampling years at Grayson/Shiloh (i.e., 2003-2005 and 2007 at Grayson and 1995-1997 at Shiloh), total estimated passage ranged from a high of 255,710 in 2005 to a low of 937 in 2007 (Table 1; Figure 13) and the majority of spring migrants in all years were smolts ( $>95.0 \%$; Table 4). Among all years, estimated passage was the highest during 1998 (Table 1; Figure 13) and the proportion passing as smolts was low (5.7\%) when sampling effort was intermediate. However, this estimate of

1,615,673 may be inflated and the proportion passing as smolts may be underestimated because no trap efficiency tests were conducted with fry.

For comparison, passage estimates were also calculated based on the estimated proportion of flow sampled at each site during 2008. This method produced estimates of 19,980 salmon at Waterford and 733 salmon at Grayson. These estimates are provided for the purpose of comparison only and they are not reflected in the tables and figures presented in this report.

Figure 13. Total estimated Chinook passage at Shiloh and Grayson during 1995-2008.

## Estimated Chinook Salmon Abundance and Environmental Factors

Trends in passage at Waterford and Grayson during 2008 were similar to the trends described for catch, and peaks in juvenile salmon passage coincided with storm events and a late April pulse flow event. River releases during January through mid-April ranged only from 163 cfs to 184 cfs which translated to relatively stable flow conditions in the river at Waterford. Higher pulse flows with two peaks occurred during the spring. River flow was more variable near Grayson as a result of storm run-off, particularly from Dry Creek entering at Modesto, and ranged from 233 cfs to $1,690 \mathrm{cfs}$.

During 2008 monitoring, daily average water temperatures ranged from $47.4^{\circ} \mathrm{F}$ to $70.0^{\circ} \mathrm{F}$ near Waterford (Figure 14) and from $49.6^{\circ} \mathrm{F}$ to $72.4^{\circ} \mathrm{F}$ near Grayson (Figure 15). Water temperatures generally increased through the outmigration season as ambient air temperatures increased. There were no obvious correlations between trends in passage and water temperature during 2008, but comparisons between years indicate that migration occurs over a more extended timeframe during years when late spring water temperatures in the lower Tuolumne River remain cooler. Relative to earlier migrants, late spring migrants may be exposed to higher water temperatures in the Delta and higher export rates.

Figure 14. Daily estimated passage of unmarked Chinook salmon at Waterford and daily average water temperature at Hickman Bridge (RM 32) during 2008.

Figure 15. Daily estimated passage of unmarked Chinook salmon at Grayson and daily average water temperature at Shiloh (RM 3.4) during 2008.

Background turbidity was generally less than 2 NTU at Waterford (Figure 16) and less than 4 NTU at Grayson (Figure 17) during the 2008 monitoring periods. During several storm events
from mid-January through late February, spikes in turbidity were observed at Waterford ranging as high as 411 NTU, and at Grayson ranging as high as 95.7 NTU. These values were well above the range associated with normal storm run-off and were caused by erosion from extensive grading activity in the Peaslee Creek watershed. Peaslee Creek enters the Tuolumne River at river mile 45.25.

Peaks in passage on January 8-9, January 24-26, January 28-31, February 4-8, and February 2729 at Waterford, and February 1-2 and February 27-29 at Grayson coincided with periods of elevated turbidity. Unlike previous years, turbidity events at Waterford were not associated with flow changes so it appears that changes in turbidity alone can stimulate migration. At Grayson, changes in turbidity were generally associated with flow changes so it is unclear whether migration was stimulated by elevated turbidity or a combined influence of flow and turbidity factors.

The ratio of estimated total passage at Grayson relative to the estimated total passage at Waterford provides an index of survival through the river between the sites ( 24.6 miles) during years when the majority of the outmigration period is sampled. The survival index estimated for 2008 was $13.2 \%$. A survival index was not calculated for 2007 because sampling did not begin until mid-March. However, an index of 58.7\% was calculated for 2006.

Figure 16. Daily estimated passage of unmarked Chinook salmon and instantaneous turbidity at Waterford during 2008.

Figure 17. Daily estimated passage of unmarked Chinook salmon and instantaneous turbidity at Grayson during 2008.

## Chinook Salmon Length at Migration

Individual forklengths of unmarked salmon captured at Waterford during 2008 ranged from 31 mm to 151 mm (Figure 18), and daily average length gradually increased from approximately 36 mm to 90 mm over the course of the sampling period (Figure 19 and Figure 20). Most of the juvenile salmon passing Waterford during 2008 were fry measuring $30-39 \mathrm{~mm}$, followed by smolts measuring 70-99 mm (Figure 21). In total, it is estimated that 15,259 fry ( $<50 \mathrm{~mm}$ ), 1,102 parr ( $50-69 \mathrm{~mm}$ ), and 8,534 smolts ( $\geq 70 \mathrm{~mm}$ ) passed Waterford during 2008. There were a number of fish captured throughout the season that were atypical sizes for fall-run Chinook salmon production. For instance, during January through mid-March there were 54 fish much larger than the majority of juvenile salmon captured during that period (average size of larger fish was almost 50 mm larger than majority of juvenile salmon) and 11 fish in the spring that were much smaller than other juvenile salmon captured during that period ( $34-39 \mathrm{~mm}$ versus 56 115 mm ). Based on sizes, it is possible that these fish may have been spawned from out-of-basin strays of a different race.

Individual forklengths of unmarked Chinook salmon captured at Grayson during 2008 ranged from 35 mm to 117 mm (Figure 22), and daily average length fluctuated between 38 mm and 117 mm during the sampling period (Figure 23 and Figure 20). Nearly $70 \%$ of the salmon estimated to have passed Grayson during 2008 were smolts measuring $70-99 \mathrm{~mm}$ (Figure 24). In total, it is estimated that 917 fry ( $<50 \mathrm{~mm}$ ), 14 parr ( $50-69 \mathrm{~mm}$ ), and 2,352 smolts ( $\geq 70 \mathrm{~mm}$ ) passed Grayson during 2008. Similar to Waterford, a few (n=6) larger sized Chinook were also captured during January through early March.

Figure 24. Estimated Chinook passage by 10 mm fork length intervals at Grayson during 2008.

## Chinook Salmon Condition at Migration

Juveniles captured at both Waterford and Grayson during 2008 were generally healthy with no apparent signs of disease or stress. Trends in individual salmon forklength to weight completely overlapped between Waterford and Grayson (Figure 25).

Figure 25. Individual forklength and weight of individual juvenile Chinook salmon measured at Waterford and Grayson during 2008.

## Oncorhynchus mykiss (Rainbow Trout)

Nine O. mykiss were captured at Waterford between January 26 and May 23, 2008 (Table 5). One O. mykiss was classified as young-of-the-year ( $<100 \mathrm{~mm}$; 58 mm ), and eight were classified as Age 1+ (100 mm-299 mm; range: 100 mm to 268 mm ).

Two O. mykiss were captured at Grayson between February 28 and March 31, 2008 (Table 5). Both O. mykiss were classified as Age 1+ (100 mm-299 mm; range: 200 mm to 224 mm ).

## Other Fish Species Captured

A total of 16,429 non-salmonids representing at least 24 species (5 native, 19 introduced) were captured during operation of the Waterford and Grayson traps in 2008 (Table 6; Appendices C and D). Native species comprised $79 \%$ of the total non-salmonid catch, consisting primarily of
unidentified lampreys ( $\mathrm{n}=11,949$ ). Species captured at Waterford were all also recorded at Grayson and additional species only recorded at Grayson were American shad, black crappie, carp, green sunfish, inland silverside, and threadfin shad. Lampreys captured in the traps were primarily ammocoetes and were not identified to species or measured.

Table 6. Non-salmonid species captured at Waterford and Grayson during 2008. Native species are indicated in bold.
