## INTRODUCTION

## Study Area Description

The Tuolumne River is the largest of three major tributaries (Tuolumne, Merced, and Stanislaus Rivers) to the San Joaquin River, originating in the central Sierra Nevadas in Yosemite National Park and flowing west between the Merced River to the south and the Stanislaus River to the north (Figure 1). The San Joaquin River itself flows north and joins the Sacramento River in the Sacramento-San Joaquin Delta within California's Central Valley. The Tuolumne River is dammed at several locations for generation of power, water supply, and flood control - the largest impoundment is Don Pedro Reservoir.

The lower Tuolumne River corridor extends from its confluence with the San Joaquin River to La Grange Dam at river mile (RM) 52.2. The La Grange Dam site has been the upstream limit for anadromous fish migration since at least 1871.

## Purpose and History of Study

Rotary screw traps (RST) have been operated since 1995 at various locations in the Tuolumne River during the winter/spring period to meet several objectives, including monitoring the abundance and migration characteristics of juvenile salmonids and other fishes, and evaluating reachspecific survival relative to environmental conditions (Figure 1). The Turlock Irrigation District and Modesto Irrigation District ('Districts'), and the City and County of San Francisco have funded nearly all RST monitoring efforts in the Tuolumne River.

Figure 1.Location map of study area on the Tuolumne River.

Current sampling locations are Grayson River Ranch (Grayson - RM 5.2) near the mouth of the Tuolumne River and a site downstream of the city of Waterford (RM 29.8). Rotary screw trapping has been conducted annually near the mouth of the Tuolumne

River since 1995 (Shiloh in 1995-1998 and Grayson in 1999-2012) for the purpose of monitoring the abundance and migration characteristics of juvenile salmonids and other fishes. Since 2006, sampling has also been conducted annually near Waterford, about 25 miles upstream of the Grayson site, to provide comparative information on the size, migration timing, and production of juvenile fall-run Chinook salmon, as well as data on other fishes.

## METHODS

## Juvenile Outmigrant Monitoring

## Sampling Gear and Trapping Site Locations

Rotary screw traps (E.G. Solutions, Eugene, OR) were installed and operated at the Waterford and Grayson sites. The traps consist of a funnel-shaped core suspended between two pontoons. Traps are positioned in the current so that water enters the 8 ft

[^0]wide funnel mouth and strikes the internal screw core, causing the funnel to rotate. As the funnel rotates, fish are trapped in pockets of water and moved rearward into a livebox, where they remain until they are processed by technicians.

The single Waterford trap was located at RM 29.8, approximately two miles downstream of the Hickman Bridge. The trap was held in place by a $3 / 8$-inch overhead cable strung between two large trees located on opposite banks. Cables fastened to the front of each pontoon were attached to the overhead cable. Warning signs, flashing safety lights and buoys marked the location of the trap and cables for public safety. Sufficient velocity at the trap during 2010-2012 precluded the need for the "wings" used to increase catch efficiency during 2008 and a portion of 2009.

At Grayson two traps were fastened together in a side-by-side configuration, with $1 / 2$ inch Ultra High Molecular Weight (UHMW) plastic strips that were bolted to each innerpontoon at the cross-bars. The traps were positioned and secured in place by two 50 lb plow-style anchors (Delta Fast-Set model, Lewmar, Havant, UK). The anchors were fastened to the outer-pontoons of the traps using $3 / 8$-inch stainless steel leader cables (each outer-pontoon was attached to a separate in-line anchor) and the length of each leader cable was adjusted using a manual winch that was bolted to the outer-pontoon. The downstream force of the water on the traps kept the leader cables taut. Sufficient velocity at the traps during 2010-2012 precluded the need for the "weir" structure used to increase catch efficiency during 2008 and 2009.

## Trap Monitoring

Sampling at Waterford and Grayson began on January 3, 2012. The traps were operated continuously (24 hours per day, 7 days per week) until June 15, 2012, when sampling was terminated due to consistently low catch at both trapping locations.

Traps at both locations were checked at least every morning throughout the sampling period, with additional trap checks conducted as conditions required. During each trap check the contents of the liveboxes were removed, all fish were identified and counted, and any marked fish were noted. In addition, random samples of up to 50 salmon and 20 of each non-salmon species during each morning check, and up to 20 salmon and 10 of each non-salmon species during each evening check, were anesthetized, measured (fork length in millimeters), and recorded. Salmon were assigned to a lifestage category based on a fork length scale, where $<50 \mathrm{~mm}=$ fry, $50-69 \mathrm{~mm}=$ parr,
and $\geq 70 \mathrm{~mm}=$ smolt. In addition, the smolting appearance of all measured salmon and O. mykiss was rated based on a seven category scale, where $1=$ yolk-sac fry, 2 = fry, 3 = parr, $4=$ silvery parr, $5=$ smolt, $6=$ mature adult, and IAD = immature adult (Interagency Ecological Program, unpublished). Weights (to nearest tenth of a gram) were taken from up to 50 salmon each week (i.e., Monday through Sunday) and from all O. mykiss using a digital balance (Ohaus Corporation, Pine Brook, NJ). Fish were weighed in a small, plastic container partially filled with stream water, which was tared prior to measuring each individual fish. Fish were then placed in a bucket with freshwater and allowed to recover before release.

Daily salmon catch was equivalent to the number of salmon captured during a morning trap check plus the number of salmon captured during any trap check(s) that occurred within the period after the previous morning check. For example, the daily salmon catch for April 10 is the sum of salmon from the morning trap check on April 10 and the evening trap check conducted on April 9. Separate daily catch data were maintained for marked (i.e., dye inoculated fish used for trap efficiency tests) and unmarked salmon.

After all fish were measured and recorded, the traps were cleaned to prevent accumulation of debris that might impair trap rotation or cause fish mortality within the liveboxes. Trap cleaning included removal of debris from all trap surfaces and from within the liveboxes. The amount of debris load in the livebox was estimated and recorded whenever a trap was checked.

## Trap Efficiency Releases

Trap efficiency tests using naturally produced juvenile salmon were conducted to estimate the proportion of migrating juvenile salmon sampled by the Waterford trap. Juvenile salmon captured in the trap were used to conduct tests whenever catches were sufficient. Twently groups of naturally produced juvenile salmon (ranging in number from 30 to 96 fish) were marked and released at RM 30 (about 0.2 miles upstream of the Waterford trap) between January 7 and April 29 to estimate trap efficiencies at the Waterford trap. Catches of naturally produced juvenile salmon at Waterford after April 29th were insufficient for trap efficiency tests. Likewise, catches of natural fish throughout the study period were insufficient for trap efficiency tests to be conducted at Grayson. Additionally, hatchery produced fish were not available for tests during 2012. Trap efficiency calculations for both sites are discussed in further detail below.

## Marking Procedure

At the Waterford trapping site, naturally produced juvenile salmon were marked onshore immediately adjacent to the trap and were then transported to the release site where they were held until release. A photonic marking system was used for marking all of the release groups because of the high quality of marks and the ability to use the marking equipment in rapid succession. All fish were anesthetized with Tricaine-S before the appropriate mark was applied. A marker tip was placed against the caudal fin and orange photonic dye was injected into the fin rays. The photonic dye (DayGlo Color Corporation, Cleveland, OH ) was chosen because of its known ability to provide a highly visible, long-lasting mark.

## Holding Facility and Transport Method

Juvenile salmon were transported from the marking sites to the release sites in either 5gallon buckets or 20 -gallon insulated coolers depending on the number of fish, temperature, and distance traveled.

At the release sites, fish were held in livecars constructed of $15^{\prime \prime}$ diameter PVC pipe cut into 34 " lengths (Figure 2). A rectangle approximately 6 " wide by 23 " long was cut longitudinally along the pipe and fitted with aluminum or stainless steel mesh. Livecars were tethered to vegetation or other structures and kept in areas of low water velocity to reduce fish stress.

Figure 2. Livecar used for holding trap efficiency test fish.

## Pre-release Sampling

Prior to release, marked fish were sampled for length and mark retention. Fifty fish (or the entire release group if fewer than 50 fish) were randomly selected from each release group, anesthetized, and examined for marks; the remaining fish in each group were enumerated. Mark retention was rated as present or absent. A total of zero fish in 2012 were found to have no marks upon examination, consequently, all fish released were presumed to have visible marks.

## Release Procedure

All marked fish were released after dark. Livecars were located several feet away from the specific release point and fish were poured from the live cars into buckets for release. Fish were released by placing a dip net into the bucket, scooping up a "net-full" of fish and then emptying the fish into the river, and allowing them to swim away. After releasing a "net-full" of fish, about 30 seconds to 3 minutes elapsed before another group of about a "net-full" was released. The amount of time between "net-full" releases varied depending on how fast fish swam away after their release. Total release time for marked groups ranged from eight minutes to 30 minutes depending on the group size.

## Monitoring Environmental Factors

## Flow Measurements and Trap Speed

Provisional daily average flow for the Tuolumne River at La Grange was obtained from USGS at http://waterdata.usgs.gov/ca/nwis/dv/?site no=11265000\&agency cd=USGS. Provisional daily average flow for the Tuolumne River at Modesto was obtained from the USGS at http://waterdata.usgs.gov/ca/nwis/dv/?site no=11290000\&agency cd=USGS. The Modesto flow station is below Dry Creek, the largest seasonal tributary entering the river downstream of La Grange Dam. As a result, that site includes flow associated with major winter runoff events. Two methods were used to measure the velocity of water entering the traps. First, instantaneous measurements were taken daily with a Global Flow Probe (Global Water, Fair Oaks, CA). Second, an average daily trap rotation speed was calculated for each trap, by recording the time (in seconds) for three continuous revolutions of the cone, once before and once after the morning trap cleaning. The average of the two times was considered the average daily trap rotation speed.

## River Temperature, Relative Turbidity and Dissolved Oxygen

Instantaneous water temperature was measured daily with a mercury thermometer at the trap site. Data were also available from hourly recording thermographs maintained by the Districts at both trapping sites. To measure daily instantaneous turbidity, a water sample was collected each morning and later tested at the field station with a LaMotte turbidity meter (Model 2020e, LaMotte Company, Chestertown, MD). Turbidity was recorded in nephelometric turbidity units (NTU). Instantaneous dissolved oxygen was measured during trap checks with an ExStik ${ }^{\circledR}$ II D600 Dissolved Oxygen Meter (Extech Instruments Corporation, Waltham, MA) at the trapping sites and recorded in milligrams per liter (mg/L).

## Estimating Trap Efficiency and Chinook Salmon Abundance

An estimate of the number of fish passing each site daily was generated by either expanding the catch data by the average estimated trap efficiency for the lifestage captured (Waterford) or by a trap efficiency predictor equation (Grayson).

## Waterford Trap Efficiency

There is a limited trap efficiency dataset for Waterford primarily due to the lack of fish available to conduct trap efficiency tests at a range of flows with each lifestage. The existing data are currently inadequate for developing regression relationships between trap efficiency and explanatory variables such as river flow, fish size, or turbidity. In the future, when more tests have been conducted with each lifestage over a range of flows, a multiple regression may be developed similar to the one described below for the Grayson traps. In the interim, an estimate of salmon relative abundance for the sampling season was calculated by expanding the daily number of fish by the average observed trap efficiency for each lifestage using the best available data.

Salmon fry abundance estimates were generated based on trap efficiency tests conducted at Waterford in 2012. Trap efficiency was calculated by pooling data from all release events conducted under similar conditions (i.e., fish size and flow at release), then dividing the total number of fish released by the total number of fish recovered. The resulting trap efficiency (TE) was then applied to the daily catch (DC) to estimate daily passage as follows:

## Estimated Daily Passage= DC/TE

During the majority of the parr/smolt outmigration period in 2012, flows on the Tuolumne River were less than 1,000 cfs. However, there was a 6 -day period when flows were above $1,000 \mathrm{cfs}$, which resulted in insufficient catch to conduct trap efficiency tests at Waterford. In order to mitigate for this shortcoming, efficiency estimates obtained between 1998 and 2000 during similarly high flows at $7 / 11$ (RM 38) and Deardorff (RM 35.5) were used to provide an approximate abundance estimate (fish size $60-95 \mathrm{~mm}$ FL, Stillwater Sciences 2001). Since these efficiency estimates were taken from different (but comparable) locations, a range of parr/smolt abundances were calculated for this 6day period to account for the uncertainty in trap efficiencies at Waterford during higher flows (i.e., greater than $1,000 \mathrm{cfs}$ ). The range was determined by using the lowest and highest trap efficiencies observed at both sites.

Thus, salmon abundance estimate calculations at Waterford in 2012 were based on (Table 3):

Fry:

- trap efficiency tests conducted in 2012 at Waterford $=8.6 \%$

## Parr/Smolt:

- trap efficiency tests conducted in 2012 at Waterford when flows were less than $1,000 \mathrm{cfs}=3.6 \%$
- trap efficiency tests conducted in 1998-2000 at the $7 / 11$ trap (RM 38; 1998 and 1999) and the Deardorff trap (RM 35.5; 2000) $=2.0-5.6 \%$

Rough estimates of daily passage were also calculated using the proportion of flow sampled by the trap as a surrogate for trap efficiency. The proportion of flow sampled at each site was estimated by the following equation:

$$
N_{e}=C_{d} \sqrt{\frac{V_{d}\left(3.14 * \frac{r^{2}}{2}\right)}{F_{d}}}
$$

where $N_{e}$ is the expanded daily number of fish; $C_{d}$ is the daily catch; $V_{d}$ is the daily velocity; $r$ is the radius of the trap; and $F_{d}$ is the daily flow measured at La Grange.

## Grayson Trap Efficiency

At Grayson, daily trap efficiencies were estimated based on a multiple regression equation developed using flow and trap efficiency data collected from 1999 through 2008 and 2011. Specifically, average daily river flow at Modesto, average fish size at release, and proportions of fish (natural log transformed) recovered from each release event were used to develop the following trap efficiency predictor equation (adjusted $\mathrm{R}^{2}$ $=0.62$ ):

Daily Predicted Trap Efficiency= EXP(-0.479988+(-0.00043*flow at MOD)+($0.03153^{\star}$ fish size))
whereflow at MOD= daily average river flow (cfs) at Modesto fish size= daily average fork length (mm) of fish captured at Grayson

These daily predicted trap efficiencies (DPTE) were then applied to the daily catch (DC) to estimate daily passage as follows:

## Estimated Daily Passage= DC/DPTE

## RESULTS AND DISCUSSION

## Chinook Salmon

## Number of Unmarked Chinook Salmon Captured

Juvenile salmon sampled in the 2012 RST operation were the progeny of an estimated 2,817 salmon (712 females) that spawned in the fall of 2011 (Cuthbert et al. 2012). Further, there were 213 adult Chinook that were not identified to sex.

The fall-run juvenile salmon outmigration in the San Joaquin Basin typically occurs during the winter and spring, extending mainly from January through May. The outmigration consists largely of fry in winter that are typically less than 50 mm fork length, and smolts in spring, which are typically greater than 69 mm fork length. There are also some larger fish that migrate mostly in winter and some fry observed in late spring, which may be from salmon with different spawn timing than fall-run.

During 2012, catches of juvenile Chinook salmon at Waterford were highest in midJanuary to mid-March, peaking on January 11, and primarily consisted of fry (<50 mm; Figure 3). Daily salmon catch did not correlate with any significant changes in environmental variables (Figure 3). Daily catches of juvenile salmon at Waterford between January 3 and June 15 ranged from zero to 146 fish, with a total catch of 3,696 salmon (Figure 3).

At Grayson, catches of juvenile salmon in 2012 were highest in April and May during the smolt outmigration period. Daily catches of juvenile salmon at Grayson between January 3 and June 15 ranged from zero to 8 fish (Figure 4), with a total catch of 85 salmon (Table 2).

Table 2. Catch by lifestage at Waterford and Grayson, 2012.

| Trapping Site | Fry (<50 mm) | Parr (50-69 mm) | Smolt ( $\geq \mathbf{7 0} \mathbf{~ m m}$ ) |
| :---: | :---: | :---: | :---: |
| Waterford | 2,390 | 473 | 833 |
| Grayson | 8 | 13 | 64 |

The length of the sampling season and the trap efficiencies will affect the total RST catch for any given season. Sampling at Waterford is generally considered comprehensive, covering January through May each year the trap was sampled. However, in 2006 the sampling was initiated a few weeks later than usual and there was an extended non-sampling period (April 12-21) due to high flows; therefore, outmigration was not fully sampled during the 2006 season. Trap efficiency decreases
at higher flows, specifically when flows are higher than approximately $1,000 \mathrm{cfs}$. During 2012, flows were less than 1,000 cfs with the exception of a 6 -day period when flows reached approximately $2,100 \mathrm{cfs}$.

Total annual trap catch at Waterford from 2006-2012 ranged from a high of 9,106 in 2006 to a low of 2,281 in 2010, and averaged 4,260 juvenile salmon (Figure 5). In 2012, the total annual catch of juvenile salmon at Waterford was approximately less than the previous year and similar to 2007-2009 (Table 1; Figure 5). The total catch in 2006 was almost 2.5 times the number of Chinook captured in 2012, despite the abbreviated sampling during that year. The variation in catch during 2006 is likely due to environmental conditions, specifically high flows that averaged approximately 5,300 cfs during the juvenile migration season (i.e., January-May/June) and the higher overall abundance. The lower catch in 2010 is likely due to environmental conditions during the smolt outmigration period when flows averaged approximately 2,400 cfs and the lower overall abundance.

Total annual catch of juvenile salmon has varied substantially between years at Grayson/Shiloh (Table 1; Figure 6). This variation is likely due to differences in one or more factors including, the duration and timing of the sampling periods, environmental conditions, and overall fish abundance and survival (Table 1). Sampling periods have varied between years, with sampling initiated as early as January or as late as April and continuing through May/June.

During 1999-2002, 2006, and 2008-2012, sampling at Grayson encompassed the majority of the expected winter/spring outmigration season (i.e., January-May/June) and can be described as comprehensive (Table 1; Figure 6). In contrast, sampling was only conducted during the spring smolt outmigration period (i.e., April-May/June) in 19951997 at Shiloh and 2003-2005 and 2007 at Grayson, therefore sampling was incomplete for those years. Sampling during 1998 began in February but was limited to a single trap (Note: two traps were operated in all other years); thus, 1998 sampling covered an intermediate proportion of the entire outmigration period. The proportion of the Jan-May outmigration period monitored each year ranged from $82 \%$ to $98 \%$ during winter/spring sampling years, from $24 \%$ to $44 \%$ during spring-only sampling years, and was $70 \%$ in the intermediate sampling year (Table 1). The proportion of the outmigration period sampled may not be representative of the proportion of the juvenile population migrating during the sample period because the migration pattern is not uniform. Migration timing can be influenced by environmental factors such as flow and turbidity,
which are often highly variable during the outmigration period.
Of the winter/spring sampling years, total annual trap catch at Grayson ranged from a high of 19,327 during 1999 to a low of 52 during 2010, and averaged 3,218 juvenile salmon (Figure 6). In all years of spring-only sampling, catches ranged from a high of 1,239 during 2001 to a low of 27 during 2007.

Figure 5. Total annual salmon catch at Waterford during 2006-2012.

Figure 6. Total annual salmon catch at Shiloh/Grayson during 1995-2012.

## Trap Efficiency

Twenty trap efficiency tests were conducted during 2012 at Waterford using naturally produced salmon fry and parr/smolt at low flows (i.e., less than 1,000 cfs). Results from these tests ranged from 0\% to $26.7 \%$ at flows (La Grange) between 219 cfs and 368 cfs (Table 3).

As mentioned previously, since there were no comparable trap efficiency data available for the Waterford trap during high flows (i.e., greater than $1,000 \mathrm{cfs}$ ), a range of parr/smolt abundances were calculated for a 6 -day period when flows exceeded 1,000 cfs that was based on data from past test results conducted under similar flow conditions at the 7/11 (RM 38) and Deardorff (RM 35.5) traps (Table 3; Stillwater Sciences 2001).

Table 3. Trap efficiency results used to estimate daily trap efficiencies at Waterford. Note: Only releases for the fry lifestage were conducted in 2012. Historical trap efficiency data from the 7/11 (RM 38) and Deardorff (RM 35.5) traps were used during the parr/smoltlifestage.

np=not provided
At Grayson, observed trap efficiency estimates from 1999-2008 and 2011 were used to derive the regression equation for predicting daily trap efficiencies, and the observed efficiencies ranged from zero to $21.2 \%$ at flows (Modesto) ranging between 280 cfs and 7,942 cfs (Table 4; Figure 8).

Daily predicted trap efficiency, and daily estimated passage at Waterford and Grayson in 2012 are provided in Appendices A and B, respectively.

Table 4. Trap efficiency results from 1998-2008 and 2011 used to derive the regression equation for predicting trap efficiencies at Grayson.

Figure 7. Trap efficiency estimates at Waterford relative to river flow at La Grange (LGN) during 2012.

Figure 8.Trap efficiency observations at Grayson relative to river flow at Modesto (MOD), 19992008 and 2011.

## Estimated Chinook Salmon Abundance

As mentioned previously, in order to account for the uncertainty in trap efficiencies at Waterford during periods of parr/smolt outmigration during high flow periods (i.e., May 8-May 13), a range of abundances were calculated using trap efficiency data from previous study years. In this section, for ease of explanation, the population estimate was calculated using the median historical efficiency with the range in parentheses (Figure 9). Based on calculated daily passage estimates, an estimated 68,462 (67,54669,378 ) Chinook salmon passed Waterford during 2012, of which 38.9\% (38.1\%-39.6\%) were smolts (Table 5). In comparison, the percentage of fish passing Waterford as smolts was $3.7 \%$ in $2011,70.7 \%$ in $2010,51.7 \%$ in 2009 , $34.3 \%$ in 2008, and $51.1 \%$ in 2007. In 2006, sampling efforts were affected by high spring flows resulting in passage estimates that were likely underestimated (particularly for smolts). In 2012, and in previous years, a majority of the salmon observed passing Waterford prior to mid-March were fry and passage was then dominated by smolts from late-March through June (Table 5; Figure 10). Daily estimated salmon passage at Waterford ranged from 0 to 3,600 . The peak in daily passage for fry occurred on January 11 and smolt passage peaked on April 3 (Figure 11).

An estimated 2,969 unmarked Chinook salmon passed Grayson during 2012 and of these, $1.6 \%$ were fry and $81.7 \%$ were smolts (Table 5). Daily estimated passage at Grayson ranged from 0 to 451 salmon. Peak daily passage for smolts occurred on May 11 (Figure 11). During comparable seasonal sampling in previous years at Grayson (i.e., winter/spring sampling in 1999-2002, 2006, and 2008-2012), total estimated passage ranged from a high of 869,636 in 1999 to a low of 2,969 in 2012 (Table 1; Figure 14); the proportion of passage as smolts was the highest in 2010 ( $95.9 \%$ ) and the lowest in 1999 (2.9\%). In spring-only sampling years at Grayson/Shiloh (i.e., 20032005 and 2007 at Grayson and 1995-1997 at Shiloh), total estimated passage ranged from a high of 254,981 in 2005 to a low of 905 in 2007 (Table 1; Figure 14); the vast majority of migrants in all spring-only years were smolts ( $\geq 95.0 \%$; Table 5 ). Among all years, estimated passage was the highest during 1998 (Table 1; Figure 14), when sampling effort was intermediate and the proportion passing as smolts was low (5.7\%). However, the 1998 passage estimate of $2,176,667$ fish may be inflated and the proportion passing as smolts may be underestimated because no trap efficiency tests were conducted with fry. In 1998, estimates for trap efficiency only existed for smolts, which were subsequently applied to other life stages. The use of smolt-specific (low) capture probability to extrapolate on fry captures may result in drastic overestimation of fish passage.

During the 2011-12 spawning season, approximately 96 (95-97) juveniles were produced per female spawner, based on the estimated 712 female spawners ${ }^{4}$ and the total estimated passage at the Waterford trap. This is low compared to 1,291 (1,2721,310 ) in 2011, 490 (337-643) juveniles per female in 2010, 175 in 2009, 311 in 2008, and 205 in 2007 (Table 6). Approximately $78 \%$ of the female Chinook salmon observed at the Tuolumne River weir were less than 700 mm indicating they were most likely twoyear old fish (Cuthbert et al 2012), which would explain the low female spawner to juvenile ratio.

[^1]

Figure 9. Daily estimated abundance of Chinook salmon at Waterford based on trap efficiencies conducted in 2012 at Waterford during the fry periodand at the 7/11 and Deardorff traps in 19982000 (at flows > 1,000cfs) for the parr/smolt period. A range of abundances were calculated for the parr/smolt period and the median and range are presented in this graph.

Table 5. Estimated passage by lifestage at Waterford and Grayson during 1995-2012. *For 20102012 the estimated passage values used in this table for Waterford are the median values of the estimated ranges.

Figure 12. Daily estimated passage of unmarked Chinook salmon at Grayson and river flow at Modesto (MOD) during 2012.

Figure 13. Total estimated Chinook passage at Waterford (2006-2012). *Note that 2010-2012 estimates are based upon the median of historical trap efficiency.

Figure 14. Total estimated Chinook passage at Shiloh and Grayson during 1995-2012. The color of the column defines the sampling period for that year.

## Estimated Chinook Salmon Abundance and Environmental Factors

Peaks in salmon fry passage at Waterford in the winter were generally associated with changes in flow, rainfall and peaks in turbidity conditions. River releases were relatively stable during this period (January-mid-March) and ranged from 325 cfs to 368 cfs. River flow near Grayson during the winter period was slightly more variable as a result of storm run-off, particularly from Dry Creek entering at Modesto, and ranged from 413 cfs to 585 cfs. During the spring (mid-March through June), higher pulse flows produced a few peaks in flow at both traps (Figure 11 and Figure 12). Smolt peaks were observed at the Grayson traps that coincided with the spring pulse flows (Figure 12).

During 2012 monitoring, daily average water temperatures ranged from $47.3^{\circ} \mathrm{F}$ to $77.3^{\circ} \mathrm{F}$ at the Waterford trap (Figure 15) and from $46.3^{\circ} \mathrm{F}$ to $77.4^{\circ} \mathrm{F}$ at the Grayson traps (Figure 16). Water temperatures generally increased throughout the outmigration season. There were no obvious correlations between trends in fry passage and water temperature during 2012 (Figure 15), but smolt passage appeared to peak with slight fluctuations in temperature at both traps during the spring (Figure 16).

Figure 15. Daily estimated passage of unmarked Chinook salmon and daily average water temperature at the Waterford trap during 2012. NOTE: From May 8-May 13 the graph depicts median daily passage estimates - See Figure 9.

Figure 16. Daily estimated passage of unmarked Chinook salmon and daily average water temperature at the Grayson trap during 2012.

Background turbidity was generally less than 4.5 NTU at Waterford (Figure 17) and less than 10 NTU at Grayson (Figure 18) during the 2012 monitoring period. During storm events (Figure 19), increases in turbidity were observed but only ranged as high as 9.5 NTU at Waterford. Increases in turbidity at Grayson ranged as high as 38.5 NTU following a storm event (Figure 18). Peaks in passage generally occurred one to several days after periods of elevated turbidity at both trapping sites.

The ratio of estimated total passage at Grayson relative to the estimated total passage at Waterford provides an index of survival through the river between the sites (24.6 miles) during years when the majority of the outmigration period is sampled. The survival index for 2012 was $4.3 \%$, which is the lowest survival index. Survival indices for 2008-2012 are provided in Table 7. Survival indices were not calculated for 2006 and 2007 because of incomplete sampling seasons. The survival indices for 2010 and 2011 should be interpreted with caution since the entire parr/smolt outmigration was calculated based on a range of trap efficiencies at an alternate site since no trap efficiency data exists at Waterford during high flows (i.e., > 1,000 cfs).

Table 7. Survival index through the lower Tuolumne River between Waterford and Grayson.

| Year | Survival Index |
| :---: | :---: |
| $\mathbf{2 0 0 8}$ | 13.2 |
| $\mathbf{2 0 0 9}$ | 11.7 |
| $\mathbf{2 0 1 0}$ | 9.9 |
| $\mathbf{2 0 1 1}$ | 20.7 |
| $\mathbf{2 0 1 2}$ | 4.3 |

Figure 18. Daily estimated passage of unmarked Chinook salmon and instantaneous turbidity at Grayson during 2012.

Figure 19. Daily rainfall measured at Don Pedro Reservoir and instantaneous turbidity at Waterford during 2012.

## Chinook Salmon Length at Migration

Individual fork lengths of unmarked salmon captured at Waterford during 2012 ranged from 21 mm to 119 mm (Figure 20), and daily average length gradually increased from approximately 33 mm to 92 mm during the course of the sampling period (Figure 21 and Figure 22). Most of the juvenile salmon passing Waterford during 2012 were fry measuring $30-39 \mathrm{~mm}$ (Figure 23). In total, it is estimated that 29,429 fry ( $<50 \mathrm{~mm}$ ), 12,594 parr ( $50-69 \mathrm{~mm}$ ), and 26,627 smolts ( $>70 \mathrm{~mm}$ ) passed Waterford during 2012 (Table 5). Individual fork lengths of unmarked Chinook salmon captured at Grayson during 2012 ranged from 30 mm to 120 mm (Figure 24), and daily average length ranged between 30 mm and 103 mm during the sampling period (Figure 25 and Figure 26). More than $80 \%$ of the salmon estimated to have passed Grayson during 2012 were smolt measuring greater than 69 mm , followed by $16.8 \%$ passing as parr measuring $50-$ 69 mm (Figure 26). In total, it is estimated that 46 fry ( $<50 \mathrm{~mm}$ ), 498 parr ( $50-69 \mathrm{~mm}$ ), and 2,969 smolts (>70 mm) passed Grayson during 2012 (Table 5).

Figure 26. Length-frequency histogram of estimated Chinook passage ( 10 mm fork length bins) at Grayson during 2012.

Chinook Salmon Condition at Migration
Juveniles captured at both locations (Waterford and Grayson) during 2012 appeared healthy without visually discernible signs of disease or stress. The length-weight relationship for individuals captured at both sites showed a very similar trend (Figure 27 and 28).

Waterford

Figure 27. Length-weight relationship of fish measured at Waterford during 2012.

## Grayson

Figure 28. Length-weight relationship of fish measured at Grayson during 2012.

## Oncorhynchus mykiss (Rainbow Trout/Steelhead)

One O. mykiss was captured at Waterford and zero were captured at Grayson in 2012. Total annual O. mykiss catch at the Grayson and Waterford traps between 2000 and 2012 ranged from 0 to 11 (Figure 29).

Figure 29. Date, size and location of O. mykiss captured at Waterford (W) and Grayson (G).

## Other Fish Species Captured

A total of 4,047 non-salmonids representing at least 22 species (6 native, 16 introduced) were captured during operation of the Waterford and Grayson traps in 2012 (Table 8; Appendices C and D). Native species comprised $65 \%$ of the total non-salmonid catch, consisting primarily of Sacramento sucker ( $n=2,427$ ). Most species captured at Waterford were also recorded at Grayson. Additional species only recorded at Waterford were redeye bass and striped bass. Species only recorded at Grayson were black crappie, hitch, inland silverside, largemouth bass, warmouth, and white catfish. Lampreys captured in the traps were primarily ammocoetes and were not identified to species or measured. No adult lamprey were captured at either trapping location.

Table 8. Non-salmonid species captured at Waterford and Grayson during 2012. Native species are indicated in bold.

## Appendix E. Key to species codes.

| BAS | Unidentified bass |
| :--- | :--- |
| BGS | Bluegill |
| BKB | Black bullhead |
| BKS | Black crappie |
| BRB | Brown bullhead |
| C | Carp |
| CHC | Channel catfish |
| CHN | Chinook |
| GSN | Golden shiner |
| HCH | Hitch |
| HH | Hardhead |
| LAM | Lamprey, unidentified species |
| LMB | Largemouth bass |
| MQK | Mosquitofish |
| MSS | Inland silverside |
| PRS | Prickly sculpin |
| REB | Redeye bass |
| RSN | Red shiner |
| SASQ | Sacramento pikeminnow |
| SASU | Sacramento sucker |
| SMB | Smallmouth bass |
| SNF | Unidentified sunfish |
| STB | Striped bass |
| UNID | Unidentified species |
| W | Warmouth |
| WHC | White catfish |

[^0]:    ${ }^{3}$ Trap efficiency data not available for parr/smoltlifestage at high flows. A range of trap efficiencies from the $7 / 11$ (RM 38) and Deardorff (RM 35.5) traps was used to obtain a range of passage estimates in 2010, 2011, and 2012.

[^1]:    ${ }^{4}$ Excludes 213 adult salmon of unknown gender that passed upstream of the Tuolumne River weir in fall 2011.

[^2]:    ${ }^{5}$ Excludes 213 adult salmon of unknown gender that passed upstream of the Tuolumne River weir in fall 2011.
