## RE: Turlock and Modesto Irrigation Districts

Project No. 2299 - Article 58 Annual Report for 2010.
Please find the enclosed 2010 Lower Tuolumne River annual report submitted to the Commission pursuant to Article 58 of the license for Project No. 2299 ( 76 FERC IT 61,117) and ordering paragraph (B) of the April 3, 2008 Order on Ten-Year Summary Report Under Article 58 ( 123 FERC | 62,012). In addition to annual updates of Project operations and ongoing Chinook salmon monitoring activities required under Article 58, the annual report includes $O$. mykiss population estimates and acoustic tracking study results required under ordering paragraph (C) of the April 3, 2008 Order. If you have any questions, please contact Robert Nees at 209-883-8214.

Respectfully submitted,

Greg Dias
Project Manager

Robert M. Nees

Attachment B: 2010 Technical Advisory Committee Materials

## Introduction

This is the Districts' 15th annual report to the Federal Energy Regulatory Commission (FERC) in a series begun pursuant to Article 58 of the July 31,1996 Order on FERC Project License 2299 (1996 Order) and the 1995 Don Pedro Project FERC Settlement Agreement (FSA). This is also the third annual report pursuant to the "Order on Ten-Year Summary Report Under Article 58" issued on April 3, 2008 (2008 Order).

This report covers the 2010 calendar year and contains:
(1) Fishery monitoring
(2) Other monitoring
(3) Downstream issues
(4) Hydrology, flow schedules, and river operations
(5) Status of habitat restoration
(6) Coordination and regulatory information
(7) Technical reports on fishery/habitat monitoring and flow operations

An eight volume report pursuant to Article 39 of the License was filed in 1992 (20-Year Report) and included 28 technical reports. The 1996 Annual Report was filed in 1997 pursuant to the 1996 Order and consisted of seven volumes that included information for 1992-96 as well as other material not contained in the 20-Year Report. The Article 58 annual reports filed since 1997 have been of $1-3$ volumes.

A Ten-Year Summary Report was filed in March 2005 as required by the 1996 Order and the Districts continued to file annual reports in 2005-2010. A listing of the Article 39 and Article 58 technical reports filed from 1992 to the present is included in Section 9 at the end of this report. The 2008 Order required (1) continued annual reporting by April 1 of San Joaquin River tributary salmon escapement numbers, (2) implementation of certain Oncorhynchus mykiss monitoring elements, and (3) an annual O. mykiss monitoring report most recently filed on January 15, 2011 for studies conducted in calendar year 2010.

## 1 - Fishery Monitoring

### 1.1. Fall-run Salmon Counts and Estimates

The two-year ban on commercial and sport ocean harvest was partially lifted and the Central Valley fall Chinook runs, which have been the lowest on record, showed substantial improvement. Exhibits 1 and 2 contain graphs of run estimates/counts.

### 1.1.1. San Joaquin Tributary Chinook Salmon Run Estimates

The San Joaquin River tributaries presently have primarily fall run Chinook salmon, with incidental numbers of Chinook salmon observed with other run timing outside of the September to mid-January period. The FERC Order of April 3, 2008 specified that the annual Article 58 report include a comparison the Stanislaus, Tuolumne, and Merced River Chinook salmon
escapement (run) numbers. CDFG conducts their fall-run surveys on the tributaries each year and the Districts depend on them to provide such information in a timely manner. The CDFG estimates contained here for 2010 were obtained indirectly through an online CDFG "GrandTab" compilation that was updated on March 9, 2010.

The counting weir operation initiated in 2009, was continued in both the Tuolumne and Stanislaus rivers, with counting operations beginning in September of each year. The Tuolumne weir operation was supported by the Districts and CCSF and implemented by FISHBIO consultants, whom also operated the Stanislaus counting weir. Due to high flows in the Tuolumne River, weir operation was ended earlier than in 2009, and as such, likely under estimates the total run, which typically can continue through the end of December. The 2010 fall run weir count for the Tuolumne was 766 adult Chinook salmon (through November 30, 2010) and 1,379 salmon at the Stanislaus weirs (through January 2, 2011). These counts represents an increase from the 2009 counts of 280 salmon in the Tuolumne river and 1,250 salmon in the Stanislaus river.

In contrast to those actual weir counts, the CDFG float surveys, using the customary carcass survey method by boat, resulted in preliminary 2010 fall-run Chinook population estimates (from GrandTab spreadsheet summary) of 540 salmon for the Tuolumne River and 1,086 for the Stanislaus River. It is not clear at this time if those estimates are inclusive of all river reaches or what the survey period was in 2010. As was the case in 2009, these estimates are lower than the weir counts in both rivers. The 2010 GrandTab numbers for the Merced River run are 651 (river) and 146 (hatchery) for a total of 797 . These tributary counts/estimates of 797 (Merced), 766 (Tuolumne), and 1,379 (Stanislaus) total 2,942 salmon for the basin and are graphed in Exhibit 1. Summary details for these surveys, dating back to 1973 can be found in Report 20102, while specific details for any given year are in the annual survey reports.

A draft CDFG Tuolumne River fall spawning survey report for 2009 in included here as Report 2010-1. A CDFG report for the 2010 fall run has not yet been provided. Consequently, Report 2010-2 only contains an abbreviated update for 2010, but does include tributary estimates for prior years. Report 2010-8 has a detailed review of the Tuolumne weir operation in 2010.

### 1.1.2. Sacramento and Central Valley Fall-run Chinook Salmon Estimates

Overall numbers of fall-run salmon for the entire Central Valley (including hatcheries) were much higher in 2010 with a preliminary GrandTab estimate of 163,181 (including 51,726 in hatcheries), greater than the 53,129 total in 2009 and the highest since 2006 total of 292,875. The estimate of adult fall-run in the Sacramento basin was 152,831 (PFMC 2010a), up from the prior low of 49,573 in 2009 and within the PFMC lower management target of 122,000 to 180,000 hatchery and natural area adults for the Sacramento River system. However, it was less than the PFMC preseason forecast of 245,483 (PFMC 2010b). A partial ban on the commercial and sport salmon fishery was implemented for California during 2010, following two years of a total ban during 2008-2009.

The total number of estimated 2-year olds in the Sacramento basin was 27,483, an indication that the cohort of 3-year olds (year class from 2008 runs) in 2011 runs may be higher (PFMC 2010b).

The PFMC uses those estimates in their Sacramento Index (SI) as a predictor of population abundance for fishery management purposes. The SI forecast for the 2011 Sacramento basin is 729,893 adults ( $95 \% \mathrm{CI}=231,671-1,228,114$ ), so some ocean harvest is being considered for 2011. Exhibits 1 and 2 contain graphs of historical harvest and abundance data through 2010.

### 1.2. Seine Sampling

Report 2010-3 reviews the routine seine monitoring conducted in eleven surveys during JanuaryJune 2010 at eight Tuolumne River sites from RM 50.5-3.4 and two San Joaquin River locations. A total of 386 natural Chinook salmon were caught in the Tuolumne River and none in the San Joaquin River. This was the 7th lowest number of salmon caught during the 1986-2010 period. Salmon were captured from RM 50.5-24.9 (La Grange to Charles Road).

Density of fry ( $\leq 50 \mathrm{~mm}$ ) peaked on 17 February, similar in timing to other years of the 20052010 period. The density of juveniles ( $>50 \mathrm{~mm}$ ) peaked on 30 March, which was also similar to other years in the period. Fork length (FL) ranged from 29-101 mm, fry were caught throughout the sampling season. A comparative review with other years is in Report 2010-3. The seine report classifies "juvenile" salmon as $>50 \mathrm{~mm}$, whereas the screw trap report distinguishes parr ( $50-69 \mathrm{~mm}$ ) and smolt ( $\geq 70 \mathrm{~mm}$ ) size ranges.

A total of 29 O. mykiss ( $21-51 \mathrm{~mm}$ FL) were caught in the Tuolumne River from February17May 11. A total of 15 fish species were recorded in the Tuolumne River and 10 species in the San Joaquin River during the season.

### 1.3. Screw Trapping

Report 2010-4 reviews the screw trap monitoring conducted near Waterford (RM 29.8) from January 5-June 11 and near Grayson (RM 5.2) from January 6-June 17 and includes a comparison with other years. Total salmon catches were 2,281 at the Waterford screw trap and 52 at the Grayson screw trap.

Fry ( $<50 \mathrm{~mm}$ ) capture at the Waterford screw trap occurred from January 19 through mid-May with an estimated passage of 10,735 for that life stage (13,399 in 2009); estimated peak passage was in late January associated with storm events and elevated turbidity. Grayson had an estimated passage of 183 fry (145 in 2009).

Waterford had a passage estimate of 1,030 parr ( $50-69 \mathrm{~mm}$ ) and 29,728 smolts ( $\geq 70 \mathrm{~mm}$ ), less than the 2009 estimates of 4,562 parr and more than the 19,213 smolts in 2009. The Grayson passage estimates showed no parr passage in 2010, compared with an estimate of 200 in 2009 and a passage estimate of 4,260 smolts in 2010, compared with 4,332 in 2009. The peak smolt passage was in mid May and was associated with higher release flows at La Grange Dam. The survival index for 2010 of $10.4 \%$, should be interpreted with caution, since there is substantial uncertainty in the total passage estimate for Waterford. Survival indices of $23.6 \%, 13.2 \%$ and $11.9 \%$ were calculated for 2006, 2008 and 2009, respectively. These estimates do not account for any salmon produced from spawning below the Waterford trap site.

There were no captures of O. mykiss at either the Waterford or Grayson traps in 2010. There were 22 other fish species captured in the screw traps in 2010.

### 1.4. Reference Count Snorkeling

Report 2010-5 reviews the snorkel surveys that were conducted on August 10-12 and November 2-4, 2010 within the RM 31.5-50.7 (Waterford to La Grange) reach of the Tuolumne River. High spring and early summer flows, due to above-normal rainfall and snowpack runoff, prevented sampling during the more typical sampling dates of June and September. The August survey was conducted at a flow of approximately 315 cfs with water temperature ranging from $11.1^{\circ} \mathrm{C}$ $\left(52.0^{\circ} \mathrm{F}\right)$ to $20.1^{\circ} \mathrm{C}\left(68.2^{\circ} \mathrm{F}\right)$. A total of 152 juvenile Chinook salmon and 268 rainbow trout (O. mykiss) were recorded in the August survey. The November survey was conducted at a flow of approximately 360 cfs with water temperature ranging from $11.7^{\circ} \mathrm{C}\left(53.1^{\circ} \mathrm{F}\right)$ to $14.3^{\circ} \mathrm{C}$
( $57.7^{\circ} \mathrm{F}$ ). A total of 170 Chinook salmon (including adult spawners) and 288 rainbow trout ( $\underline{O}$. mykiss) were recorded in the November survey.

Chinook salmon were observed downstream to Riffle 57 (RM 31.5) and rainbow trout downstream to Riffle 31 (RM 38.0) in August. Chinook salmon and O. mykiss were both observed downstream to Riffle 41A (RM 35.3) in November. Other native fish species observed were Sacramento sucker, Sacramento pikeminnow, hardhead, and riffle sculpin. The non-native species recorded were largemouth bass, smallmouth bass, redear sunfish, and striped bass. Report 2010-5 also contains a comparison with other years, dating back to 1982.

### 1.5. O. mykiss Population Estimate Surveys

This snorkeling study pursuant to the 2008 FERC Order was first done in July 2008. There were surveys conducted in March and July of 2009 and the 2009 report was submitted to FERC on January 15, 2010. In 2010, surveys were conducted in March and April, with the 2010 report submitted to FERC on January 15, 2011. Two separately required O. mykiss annual monitoring reports were also submitted in January 2010 and January 2011 along with the population estimate reports which summarized, among other monitoring results, the outcome of the population estimate surveys.

Report 2010-6 presents the population estimates for O. mykiss and Chinook salmon based on surveys conducted in 2010 and provides a comparison of these results with those from previous surveys. The population estimates are based on babitat mapping completed in 2008 (RM 52.039.5) and 2009 (RM 39.5 - 29.0).

The O. mykiss population estimates from habitat-specific counts (in parentheses) for YOY/juvenile ( $<150 \mathrm{~mm}$ FL) and adult ( $>150 \mathrm{~mm} \mathrm{FL}$ ) were:

- July 2008: 2,472 (128) YOY/juvenile and 643 (41) adult O. mykiss
- March 2009: 63 (5) YOY/juvenile and 170 (7) adult O. mykiss
- July 2009: 3,475 (641) YOY/juvenile and 963 (105) adult O. mykiss
- March 2010 ${ }^{1}$ : 109 (13) adult O. mykiss
- August 2010: 2,405 (313) YOY/juvenile and 2,139 (324) adult O. mykiss

Both the March and August 2010 surveys extended from RM 51.8 to RM 38.4. In March, O. mykiss were observed down to RM 38.5 and in August to RM 39.7. The August 2010 juvenile O. mykiss population estimate was lower than the July 2009 estimate and similar to the July 2008 estimate juveniles. The summer population estimates are within the $95 \%$ CI for juvenile $O$. mykiss in all three years (2008-2010). The August 2010 adult $O$. mykiss population estimate was higher than both the July 2009 estimate and the July 2008 estimate. The March 2010 adult estimate was similar to March 2009.

The comparable estimates for Chinook salmon (O. tshawytscha) in these surveys were:

- July 2008: 2,636 (96) YOY/juvenile
- March 2009: 39,563 (4,281) YOY/juvenile
- July 2009: 29,389 (4,696) YOY/juvenile
- March 2010: 6,141 (574) YOY/juvenile
- August 2010: 6,338 (973) YOY/juvenile

As in previous years, most of the salmon in the surveys were in the 50-99 mm range. The 2010 estimate of juvenile salmon in March was much lower than the March 2009 estimate, with the August 2010 estimate higher than in July 2008 but lower than in July 2009. There were also 14 adult Chinook salmon (>150 mm FL) observed from RM 50.6-48.1 in August 2010.

### 1.6. O. mykiss Acoustic Tag and Tracking

This tracking study pursuant to the May 2010 FERC Order was initiated by FISHBIO in March 2010 after permits required to initiate the adult $O$. mykiss tracking study were obtained. The initial study was conducted from March through November 2010. Report 2010-7 presents results from the 2010 study and shows little movement of tagged fish beyond approximately 500 meters ( 0.31 miles) of their release location, with no tagged fish from the study detected downstream of RM 44. The study is scheduled to include continuation of tracking fish tagged in the fall of 2010 through spring of 2011, with recommendations for an additional tagging effort in fall of 2011 and subsequent tracking through spring of 2012.

### 1.7. Counting Weir

The year 2010 represents the second consecutive year in which the counting weir was operational on the Tuolumne River. A similar weir has been in operation on the Stanislaus River since 2003. Report 2010-8 provides detailed results and sampling conditions for the Tuolumne River weir during the 2010 Fall/Winter monitoring season, which totaled 766 adult Chinook salmon counted for the lower Tuolumne River. The weir was deployed at RM 24.5 from September 9 through November 30 when flood management releases necessitated removal of the weir. The 2010 monitoring period thus represents an underestimate of the total escapement,

[^0]which typically continues through December. As discussed in report 2010-1, the weir count does not include fish spawning downstream of RM 24.5. Lastly, the high flows in December 2010 also prevented CDFG spawner surveys and these results (not yet published) will also represent an underestimate of the actual spawner population for 2010.

## $\underline{2}$ - Other Monitoring

### 2.1. Temperature

Daily average thermograph data and daily max-min air temperatures are graphed in Part 2 of Attachment A. Complete thermograph data for the Tuolumne and San Joaquin Rivers are posted at the TRTAC website, http://tuolumnerivertac.com/data.htm.

## 3 - Downstream Issues

Important factors influencing salmonid populations occur downstream of the Tuolumne River from the San Joaquin River to the Pacific Ocean where they spend most of their life. Some of these are reviewed in this section. Exhibits 3 and 4 have information on the size and numbers of salmon captured in sampling efforts from lower tributary stations, the SJR, and the South Delta. Those include screw trap, trawl, and export salvage sampling programs within the January-June season that spans the juvenile salmon (fry to smolt) rearing and migration period. Fry density increased in 2010 compared with 2009 for the Mossdale trawl catch and remained similar in the export salvage.

### 3.1. Ocean Conditions

Central Valley Chinook salmon spend the majority of their lives in the eastern Pacific Ocean and the influence of ocean conditions on their growth and survival is widely recognized (Williams, 2006). Temperature, upwelling, and general productivity of the Northern California Current varies considerably from year to year and the understanding of that environment has increased in recent years. The Northwest Fisheries Science Center (NWFSC) reported "extremely mixed" signals of ocean ecosystem indicators, with a cooling trend interrupted in by warming from fall 2009 through spring 2010. However, in May 2010 the cooling trend resumed and ocean conditions have remained cold since the summer 2010, suggesting that ocean conditions for salmon in 2011 may be "among the best of the past 15 years" (details available at NWFSC website http://www.nwfsc.noaa.gov/research/divisions/fed/oeip/g-forecast.cfm). The effects of ocean conditions may not be evident for years until salmon cohorts (year classes) return to spawn. In addition, conditions for southern salmon populations (i.e. Central Valley salmon) may differ from those reported by the NWFSC, particularly as related to the continuing decline of Sacramento River and other Central Valley fall-run salmon populations.

NOAA fisheries reported results from the first phase of a Chinook salmon ocean distribution mapping study (http://swfsc.noaa.gov/news.aspx?ParentMenuId=54\&Division=FED\&id=16373) that suggested Central Valley salmon stocks may still be depressed based on initial counts in Oregon and California. An additional NOAA fisheries report on genetic stock identification of Chinook salmon from the Monterey Bay recreational fishery in 2010 estimated that " $94 \%$ of the
catch was Central Valley Fall Run Chinook, which is similar to the proportion in 2006, when this stock was relatively abundant, and substantially higher than in 2007, which was the first year of the stock "collapse"".
(http://swfsc.noaa.gov/news.aspx?ParentMenuId=54\&Division=FED\&id=16266)

### 3.2. Delta Issues

### 3.2.1. Salmon salvage and losses at Delta water export facilities

Exhibit 4 contains 2010 State Water Project (SWP) and Federal Central Valley Project (CVP) delta water export facility salmon salvage and loss information. Additional review will be available in SJRGA (In Progress). Natural/unmarked salmon salvage for January-June at the facilities was higher in 2010 with combined facility estimates of 9,325 salmon salvaged compared with 7,115 in 2009. The number of salmon losses at the facilities was similar in 2010 compared with 2009 ( 14,203 and 14,295, respectively). The reported numbers do not include associated indirect losses within the Delta, plus the salvage loss estimates for fry (mostly in JanMar) may be inherently low due to reduced screening efficiency. It is not known how many of these salmon were from the San Joaquin basin, but salmon within the same size range and timing are recorded in catches from tributary and mainstem (Mossdale) sampling programs (Exhibit 3).

Few salmon fry ( $<50 \mathrm{~mm}$ ) were reported at the facilities from January-March, but there was a dominant salvage of larger juveniles/smolts (75-110 mm) from late March through late May. Weekly density (combined salvage and loss/1000 AF of export) was during April and May at both facilities.

### 3.2.2. Spring smolt conditions and evaluation

The San Joaquin River Agreement (SJRA) and the Vernalis Adaptive Management Plan (VAMP) are elements for meeting the objectives of the 1995 State Water Resources Control Board (SWRCB) Bay-Delta Water Quality Control Plan over a 12 year period beginning in 2000, pursuant to SWRCB Decision 1641. The program includes a 31-day period, from about mid-Apr to mid-May, with an experimental combination of salmon protective measures: specified San Joaquin River flows at Vernalis, Head of Old River Barrier (HORB), and reduced State and Federal delta exports. The Tuolumne River outmigration pulse volume has been scheduled to partly coincide with the VAMP period, accounting for a 2-day lead time for flows from La Grange to arrive at Vernalis, and to provide transition days to and from base flows. An additional Tuolumne River spring pulse flow volume of up to 22,000 acre-feet (AF) from TID/MID, supplemental to FERC pulse allocations, can be required under the SJRA to help meet target flows at Vernalis.

During WY 2010, flows of 3,000 cfs at Vernalis were targeted for acoustic tracking studies during April 1-24 and May 26-31 (the D-1641 requirement for Vernalis flows during these periods is expected to range from 1,420 to $2,280 \mathrm{cfs}$ ). For the April 25 -May 25 test period, flows of 3,200 cfs were targeted at Vernalis and the daily combined CVP and SWP export rates were limited to no more than 1,500 cfs from April 1 through May 31. Actual flows at Vernalis during the VAMP test were approximately $5,900 \mathrm{cfs}$. Flows in the Tuolumne River exceeded the

VAMP requirement during this time period due to flood management releases (See Attachment A3).

The 2010 VAMP smolt tracking study used a total of 1,004 hatchery smolts with implanted acoustic transmitters, representing the 5th year that acoustic technology was used to estimate juvenile salmon survival through the southern Sacramento-San Joaquin Delta (VAMP 2010). There were 7 releases made in 2010 of about 72 smolts each during April and May at Durham Ferry on the San Joaquin River, with other release locations near Stockton, CA and in Old River. Tracking incorporated the use of several stationary receivers downstream into the central delta, including evaluation arrays near the behavioral barrier and the export facilities, and a mobile receiver. Similar to 2009, a non-physical barrier at the Head of Old River was tested in 2010, incorporating some design and deployment modifications. No study results for the 2010 study are available at this time. However, preliminary indications are that receiver performance at the monitoring stations improved in 2010 and that survival estimates should be available for all release groups. Mortality of smolts was also noted as being lower in 2010 from Durham Ferry to the upper Old River junction than in 2009 (VAMP 2011). The VAMP tagging study is planned to continue in 2011 with some proposed changes in the timing and release numbers made at Durham Ferry (VAMP 2011).

### 3.2.3. Other Delta issues

A National Research Council (NRC) panel studying sustainable water and environmental management in the California Bay-Delta held a series of meetings in 2010 at the request of Congress and the Departments of the Interior and Commerce. The panel will focus on whether there are conservation actions other than those in the biological opinions that would protect species while using less water, and to account for potential conflict between the needs of NMFS and USFWS species. More information can be found at the following websites. http://swfsc.noaa.gov/news.aspx?ParentMenuId=54\&Division=FED\&id=15970 and http://www8.nationalacademies.org/cp/projectview.aspx?key=49175 .

## 4 - Hydrology, Flow Schedules, and River Operations

The 2010 calendar year included part of the 2010 and 2011 water years (WY) from October $1^{\text {st }}$ through September $30^{\text {th }}$. The WY2010 Tuolumne River preliminary computed natural runoff was 97\% of the long-term average (http://cdec.water.ca.gov/cgi-progs/reports/FLOWOUT.201009). The 2010 San Joaquin Basin 60-20-20 Water Supply Index was 3,687,196 - an "Intermediate BN-AN" Fish Flow Year (FFY) in the Article 37 classification, which run from April $15^{\text {th }}$ through April $14^{\text {th }}$. The daily average computed natural flow, actual La Grange flow, and fish flow schedules of WYs 2010 and 2011 are graphed in Part 1 of Attachment A; actual flows at other SJR basin locations, Delta exports, Don Pedro Reservoir storage, and snow and precipitation data are also included.

Calendar year 2010 included Article 37 minimum flow and pulse flow requirements spanning the 2009 and 2010 FFYs. Part 3 of Attachment A contains the primary flow schedule correspondence. The initial volume used in the April 2010 scheduling process was 300,923 AF representing the maximum requirement due to above average runoff conditions and an increase
from the 151,222 AF scheduled in the previous year.
Flood management releases pursuant to ACOE criteria were required as the Don Pedro Reservoir storage was encroaching the designated flood control space as shown in the graph in Part 1 of Attachment A. Flood management flows generally exceeding 2,000 cfs occurred from mid-April through early-July due to above average runoff conditions. Base flows of at least 300 cfs occurred in August through October. A fall pulse volume of 5,950 AF occurred during October 6-16 and was scheduled to provide a peak of 800 cfs. Flood management flows exceeding 2,000 cfs resumed in December and continued through January 2011.
5-TRTAC Habitat Restoration Activities
As directed under the 1995 FSA, the TRTAC developed ten top priority habitat restoration projects aimed at improving both geomorphic and biological components of the lower Tuolumne River corridor. TID had acted as the Project Manager on behalf of the TRTAC for implementation of grant funding of these projects. The table below lists these projects under three catagories (Channel and Riparian Restoration, Predator Isolation, and Sediment Management).

| TRTAC Habitat Restoration <br> Projects | Channel and Riparian Restoration Projects |  |  |
| :--- | :--- | :---: | :---: |
|  | Completed in 2003. |  |  |
| Gravel Mining Reach Phase I <br> (7-11 Segment) | Design work completed. Implementation funding <br> withheld. |  |  |
| Gravel Mining Reach Phase II <br> (MJ Ruddy Segment) | Design work completed. Implementation funding <br> withheld. |  |  |
| Gravel Mining Reach Phase III <br> (Warner-Deardorff Segment) | Cost estimate developed, but no funding source was <br> ever identified. |  |  |
| Gravel Mining Reach Phase IV <br> (Reed Segment) | Predator Isolation Projects |  |  |
| Sediment |  |  | Completed in 2001. |
| Special Run-Pool (SRP) 9 | Phase I hydraulic modeling and design completed in <br> 2006. No Phase II funding for acquisition and <br> construction has been identified. |  |  |
| Special Run-Pool (SRP) 10 | Survival to emergence study and pool sand volume <br> assessment completed. Funding and permitting of <br> Riffle Cleaning to be determined. |  |  |
| Riffle Cleaning (Fine sediment) | Completed in 2007. |  |  |
| Gasburg Creek basin (Fine sediment) | Coarse Sediment Management Plan and Design <br> Manual completed in 2006. Implementation funding <br> withheld. |  |  |
| Gravel augmentation near La Grange <br> (Coarse sediment) | Completed in 2005. |  |  |
| River Mile 43 (Coarse sediment) |  |  |  |

Four of the ten identified TRTAC projects have been completed. Three other projects followed a
rigorous and competitive review/selection process, with substantial CALFED grant funding being approved. However, as reviewed in previous annual reports, funding for these projects was later withheld. Considerable FSA and the federal AFRP funds were expended for extensive related pre-project efforts, including proposal development and refinement, completion of the Habitat Restoration Plan, the Floodway Restoration Design Manual, and the Coarse Sediment Management Plan. Two of the projects were partially implemented, and the remaining project (Gravel Mining Reach Phase IV) had a cost estimate developed and was pending completion of the prior channel restoration projects.

Funding for a CALFED approved proposal to provide for three years of restoration project monitoring/river-wide monitoring was withdrawn by CDFG in 2005. At this time, no restoration project activity is occurring.

## 6 - Tuolumne River Technical Advisory Committee (TRTAC)

Four quarterly TRTAC meetings were held in 2010: March, June, September, and December; the fishery agencies attended none of the meetings in 2010. Attachment B contains the 2010 TRTAC meeting agendas, summaries, handouts, and other materials. The website (http://tuolumnerivertac.com/) was used for posting various TRTAC-related items (documents, reports, correspondence, meeting materials, etc.) and other fishery/habitat information.

## 8 - General List of Acronyms and Abbreviations

| ACOE | Army Corps of Engineers |
| :--- | :--- |
| AF | acre-feet, a measure of water volume |
| AFRP | Anadromous Fish Restoration Program (part of USFWS) |
| AMF | Adaptive Management Forum |
| AT | air temperature |
| BAWSCA | Bay Area Water Supply and Conservation Agency |
| C | degrees Celsius |
| CALFED | now known as California Bay-Delta Authority |
| CBDA | California Bay-Delta Authority |
| CCSF | City and County of San Francisco |
| CDEC | California Data Exchange Center |
| CDFG or DFG | California Department of Fish and Game |
| CDRR | combined differential recovery rate |
| cfs | cubic feet per second, a measure of flow rate |
| CRRF | California Rivers Restoration Fund |
| CSPA | California Sportfishing Protection Alliance |
| CWT | coded wire tag |
| CVP | Central Valley Project |
| CY | cubic yard |
| DPS | distinct population segment |
| DWR | Department of Water Resources |
| ESA | Endangered Species Act |
| ESU | evolutionarily significant unit |
| F | degrees Fahrenheit |
| FERC | Federal Energy Regulatory Commission |
| FL | fork length |
| FOT | Friends of the Tuolumne |
| FSA | Don Pedro Project 1995 FERC Settlement Agreement |
| FWS | see USFWS |
| HORB | Head of Old River Barrier |
| HRI | harvest rate index |
| IEP | Interagency Ecological Program |
| IFIM | Modesto Irrigation District |
| mm |  |
| MID |  |

| NHI | Natural Heritage Institute |
| :--- | :--- |
| NMFS | National Marine Fisheries Service |
| NOAA Fisheries | also National Marine Fisheries Service |
| NRCS | Natural Resources Conservation Service |
| NWS | National Weather Service |
| ORNL | Oak Ridge National Laboratory |
| PFMC | Pacific Fishery Management Council |
| R(letter and/or \#) | specific riffle (location identifier, e.g. RA7 is Riffle A7) |
| RM | river mile |
| RST | rotary screw trap |
| SJR | San Joaquin River |
| SJRA | San Joaquin River Agreement |
| SJRGA | San Joaquin River Group Authority |
| SRP | Special Run/Pool (mined area of river, usually with \#, e.g. SRP 9) |
| SWP | State Water Project |
| TID | Turlock Irrigation District |
| TRE | Tuolumne River Expeditions |
| TRT | Tuolumne River Trust |
| TRTAC | Tuolumne River Technical Advisory Committee |
| USFWS | United States Fish and Wildlife Service |
| USGS | United States Geological Survey |
| VAMP | Vernalis Adaptive Management Plan |
| WT | water temperature |
| WY | Water Year |
| YOY | Young of Year |

2005 Ten-Year Summary Report

## Exhibits

1. Spawning run estimates
1.1. San Joaquin River tributary estimates
1.2. Other Central Valley Fall-run estimates
2. Salmon harvest and Sacramento abundance data
2.1. California Chinook ocean harvest
2.2. Sacramento River Fall-run Estimates
2.3. Abundance Index and Harvest Rates
3. January-June 2010 Basin salmon rearing/outmigration data
3.1. Tributary screw trap catches and San Joaquin River (Mossdale) trawl catch
3.2. Average size in catch and delta salvage
3.3. Mossdale catch individual size and mark
4. January-June 2010 delta salmon salvage data, water exports, and basin flows
4.1. Table of weekly salvage and flow/export data
4.2. Graphs of estimated salvage/loss numbers and density (relative abundance)
4.3. Weekly average flow and exports
4.4. Size and hatchery origin of delta salvage
4.5. Daily San Joaquin Basin flows and rainfall

RE: Project 2299 - Flow Schedule for 2009-2010 and 2010-2011 Fish Flow Years
Dear Fishery Agency Representatives:
This letter pertains to aspects of Articles 37 \& 38 of the Don Pedro Project license regarding Tuolumne River flows. It contains a review of the fall 2009 flows and flow schedule information for the 2009-2010 Fish Flow Year ending April 14, 2010 and the 2010-2011 Fish Flow Year starting April 15, 2010.

## Review of Article 38 45-Day Period and Fall Pulse Flow Requirement

The Article 38 '45-Day Period' in fall 2009 began October 17 and ended November 30, as has been the default period for many years. In accordance with Article 38, reduction in river height between the end of the 45 -day period and March 31 shall not exceed four inches ( 0.33 feet) below the average height established during the 45-day period (based on the rating table for the discontinued USGS Old La Grange Bridge streamflow gage).

Using provisional daily flow data from the USGS gage below La Grange Dam, the calculated average flow was 314 cfs for the 2009 45-day period, which corresponds to a river height of 170.03 feet at the Old La Grange Bridge based on the USGS 1996 rating table. A gage elevation of 169.70 feet is 4 inches below that average and corresponds to 202 cfs as shown in Table 1. The flow schedule requirement has been 200 cfs or more since December 1, 2009. Flow releases have exceeded 202 cfs , so the flow requirement this season after the 45 -day period related to Article 38 has been met to date; the Article 38 period ends on March 31.

The Article 37 fall pulse flow allocation was 9,352 AF during the 12 days of October 12-23 and the provisional measured flows below La Grange Dam in that period totaled 14,143 AF.

## Flow Schedule for the 2009-2010 Fish Flow Year ending April 14, 2010

The most recent flow schedule letter sent to you on October 19, 2009 contained the current schedule for the Article 37 2009-2010 Fish Flow Year starting April 15, 2009 and the total annual requirement of $175,791 \mathrm{AF}$. Provisional USGS flow data (and estimated values since January 19) indicate that volume had already been released to the Tuolumne River below La Grange Dam by about March 15, 2010. Identified in the letter of October 19, 2009, there remained an unscheduled volume of 7,049 AF for the current Fish Flow Year. Several proposals and discussions have occurred among the District and the Fishery Agencies over the past three months about scheduling the $7,049 \mathrm{AF}$ remainder. A default allocation was established, shown in Table 2, which schedules that volume during the April 2-14 period, resulting in a flow of 474 cfs over 13 days to finish out the schedule for the current Fish Flow Year.

The flow schedule discussions have also considered a potential carryover to the next Fish Flow Year of $5,000 \mathrm{AF}$ of the $7,049 \mathrm{AF}$ remainder to the summer (June through September) period of 2010. The District received a letter from the Fishery Agencies e-mailed on March 12, 2010, which contained, among other issues, a recommendation to carry over $5,000 \mathrm{AF}$. The District sent an e-mail reply to the Fishery Agencies that same day with several identified concerns, stating that resolution of those issues was needed. To date there has been no resolution of those items, so the schedule in Table 2 will be followed and there will be no carryover unless mutual agreement is reached by April 1.

Flow Schedule for the 2010-2011 Fish Flow Year starting April 15, 2010
The 1996 FERC Order, Amended Article 37, contained a Water Year Classification Index for determining the annual volume of scheduled stream flows for each Fish Flow Year. The classifications are based on the San Joaquin Basin 60-20-20 Indices for water years and updated Index thresholds for determining the year type classification were contained in the letter provided to you on October 19, 2009.

TID has again been tracking the Index forecasts and providing your agencies with corresponding flow volume information in e-mails this season. Table 3 contains the Department of Water Resources (DWR) monthly forecasts and updates of those forecasts to date. The forecasts are similar to last year at this time in that there has been a wide range in potential FERC flow volume requirements at the $90 \%$ and $50 \%$ exceedence levels. In addition, there has been an extended dry period, so the potential flow volumes are expected to continue to be variable going into the 2010-2011 Fish Flow Year.

There will again be the need to coordinate the basin spring pulse flow schedule for the Vernalis Adaptive Management Program (VAMP) in 2010. TID has supplied your agencies with initial preliminary spring daily schedules for potential dry, average, and wet conditions in a March 8 email and to the VAMP Hydrology Coordinator for the March 17 VAMP technical meeting. At that meeting, the initial selection of the 2010 31-day VAMP period was from April 25 - May 25. The corresponding start of that period at La Grange would be April 23, 2008 using the customary 2-day lead time for flow to arrive at Vernalis on the San Joaquin River. As a result, consideration
of Tuolumne flows for the preceding April 15-22 period will be needed in the initial flow schedule.

Based on applying the current DWR April-July runoff forecast of March 23 to update the DWR March 1 60-20-20 Basin Index, the annual minimum Article 37 flow requirements presently are 160,065 AF (Intermediate Dry-Below Normal) in the 90\% Exceedence case and 300,923 AF (Intermediate Below Normal-Above Normal) in the 50\% Exceedence case; these values are also shown on Table 3 with the respective Basin Index. Due to the dry trend, the $90 \%$ and $50 \%$ levels are considered at present.

Based on the above, two provisional daily schedules for April 15 - June 19 consistent with the draft schedules already provided on March 8 are presented as examples (Table 4); the 2009 schedule is included for comparison. The schedules have the following features:

1) The base flow/pulse flow amounts are those specified for the year types in Article 37.
2) The overall timing of the spring pulse flow incorporates the proposed VAMP period.
3) The pulse flow pattern with multiple peaks generally corresponds to various coordinated schedules utilized in past years.
4) Rampdown (transition) flows are included.

We will need rapid consensus and approval as in prior years to (1) establish and implement the initial FERC flow schedule starting April 15 and for the VAMP scheduling process, and (2) for all subsequent schedule adjustments so that any flow modifications can be conducted in a timely manner, including adequate advance notice for the Districts to implement such operations. It is again expected that some short-term adjustments might be made within the designated VAMP period as may be necessary and feasible in accordance with the VAMP flow coordination effort. Such adjustments would preferentially be made first to any applicable VAMP supplemental flows and secondarily to the FERC pulse flows.

If you have any questions, please contact Wes Monier at 209-883-8321.

RE: Project 2299 - Final Flow Schedule for 2009-2010 Fish Flow Year under Article 37
Dear Fishery Agency Representatives:
The Fishery Agencies requested by e-mail on March 31, 2010 a modification to the schedule contained in the letter of March 25, 2010 for the remainder of the 2009-2010 Fish Flow Year ending April 14, 2010. Specifically, the scheduled flow increase was proposed to begin a day earlier on April 1,2010 and the pattern of higher flows for the April 2-14 period was proposed to be adjusted. Your agencies were notified by e-mail that same day (1) that this schedule modification could be accommodated on short notice in this case and (2) of the specific flow schedule adjustments to meet the total annual volume. The attached table includes the final flow schedule for the 2009-2010 Fish Flow Year ending April 14, 2010.

If you have any questions, please contact Wes Monier at 209-883-8321.

Robert M. Nees
Director of Water Resources and Regulatory Affairs

RE: Project 2299 - Minimum Flow Schedule for 2010-2011 Fish Flow Year

Dear Fishery Agency representatives:
Based on applying the current DWR April-July runoff forecast update of April 13 to the DWR April 160-20-20 basin index, the annual minimum flow requirement is $300,923 \mathrm{AF}$ under both the $90 \%$ Exceedence case and the $50 \%$ Exceedence case. These values are also shown on Table 1 with the respective 60-20-20 index.

Table 2 has the same daily Article 37 schedule previously provided in the March 25 letter for the $50 \%$ exceedence condition. At the present time, substantially higher flows ranging from about $1,700-2,500 \mathrm{cfs}$ in a similar pattern are initially projected to continue into at least late May. Those higher total flows have been incorporated into the VAMP operational schedule for the April 23 - May 23 period.

If you have any questions, please contact Wes Monier at 209-883-8321.

Sincerely,

Robert M. Nees
Director of Water Resources and Regulatory Affairs
C: Larry Weis - TID
Allen Short - MID
Michael Carlin - CCSF
FERC Secretary

# TECHNICAL ADVISORY COMMITTEE MEETING 

March 18, 2010 at 9:30 AM
Turlock Irrigation District, Lunch Room (2 ${ }^{\text {nd }}$ floor)

## DRAFT AGENDA

1. Introduction and Announcements
2. Administrative Items:

- Review/revise agenda
- Approve notes from Dec 2009 meeting
- Items since last meeting

3. Monitoring/Reports:

- Fall run information - weir; river surveys
- Ongoing monitoring - seine, screw trap, weir, winter snorkel survey
- 2009 annual FERC report
- Other planned studies for 2010

4. Flow Operations:

- Current watershed conditions, runoff and flow volume forecasts
- VAMP and potential spring flow schedule(s)

5. Agency/NGO updates
6. ADDITIONAL ITEMS
7. Next meeting Dates - June 10, September 9, December 9

## Summary

## 1. Introduction and Announcements

- No fishery agencies were present.
- Jesse Roseman attended from TRT.

2. ADMINISTRATIVE ITEMS:

- Review/Revise agenda - No changes
- Review notes from 11DEC - Approved
- Items produced since last meeting - reviewed the handout listing material posted at http://tuolumnerivertac.com/ Those included:
o Prior meeting agenda, summary, and handouts
o Correspondences regarding the January 15 O. mykiss monitoring report
o January 15,2010 report on O. mykiss pursuant to ordering paragraph (C)(5) of the April 3, 2008 FERC Order
o Several technical reports for the annual FERC report
o Counting weir data, seine data, and updates to the basin monitoring newsletter.

## 3. Monitoring/Reports:

- Salmon run data. Ford discussed salmon run estimates for the Tuolumne, Merced and Stanislaus Rivers and stated he was waiting for a 2009 spawning survey report from CDFG. Although CDFG reported 124 for the Tuolumne in GrandTab (excluding spawners below Fox Grove?), counting weir numbers were 280 by midJanuary, and reached 300 by the week of March 15. By comparison, CDFG reported a GrandTab Stanislaus estimate of 595 while the weir count there was 1250 by midJanuary; a handout of the daily weir counts was reviewed. Other GrandTab numbers were: Merced River with 604 (358:246 for River:Hatchery) and Mokelumne River with 2,229 (680:1549 for River:Hatchery).
- Counting weir. The weir will continue operation into April and May as flows allow (upper limit may be about 1500 cfs ).
- Seine/Screw Trapping. Handouts of size and abundance of RST salmon catch were reviewed. At Waterford, the early fry peaks were associated with storm events, but catch was low at Grayson overall. Many larger juveniles ( $80-120 \mathrm{~mm}$ ) were also caught at Waterford in January - those were not from fall 2009 run. The fall 2009 cohort catch began to include parr and smolts (50-80 mm) mainly in March at Waterford.
- O. mykiss Studies. Hume indicated that the March 2009 population estimate was complete. Ford reported that the adult O. mykiss tracking study had been approved and that the project would be initiated within the week.

## 4. Flow Operations:

- Reviewed water year forecasting based on 1 MAR $10 \%, 50 \%$ and $90 \%$ exceedance estimates (see handouts). Still a wide range between the $50 \%$ and $90 \%$ levels. VAMP flows were planned from April 25 to May 25 (at Vernalis)
- Discussions with the fishery agencies about the use of 7000 AF for pulse flows, base flow, or carryover storage were ongoing at the time of the meeting.

## 5. Agency/NGO UPDATES

- TRT
o Roseman discussed a Jeff Jardine article in the Modesto Bee about the removal of the Dennett Dam and pursuing funding sources.
o Roseman discussed a Farmwater Toolbox forum on Thursday March 25, 2010 at the UC Cooperative Extension in Merced. Details and other resources can be found at: http://agwaterstewards.org/txp/Home/
o Roseman discussed the second TRT "Paddle to the Sea" event from May 7 to June 5.

## Who is the <br> Tuolumne River Truss?

The Tuolumne River Trust is the voice for the river. We believe that by inspiring grassroots community support, we can protect our river for future generations and restore this precious ecosystem for fish and wildlife.

Since 1981, we have worked to protect this vital natural resource for our communities.

Today, with offices in Sonora, Modesto and San Francisco, our programs seek to build vibrant communities centered around the river through education, advocacy, restoration and recreation.

June 10, 2010 at 9:30 AM<br>Turlock Irrigation District, Room 152 (1st floor)

Summary

## 1. Introduction and Announcements

- No fishery agencies were present.

2. Administrative Items:

- Review/revise agenda - no changes
- Review notes from March meeting - no changes were identified
- Items since last meeting - the handout listing the material posted at http://tuolumnerivertac.com/ was reviewed. Those included the annual report to FERC, 2009 spawning survey update, 2009 counting weir report, FERC Orders partially approving O. mykiss synthesis report and study plans for IFIM and water temperature, flow schedule and study planning letters to fishery agencies (6/28 reply deadline for comments on updated study schedules).

3. Monitoring/Reports: Handouts were reviewed

- May FERC Orders on planned studies: Ward asked for details on FERC Order requirements. For the May 10, 2010 Order: 1) Population estimates will continue to be conducted in July of each yr., with reference count surveys in June, September, and Feb/Mar (or as modified due to high flows), depending on accessibility due to flow conditions. 2) Tracking study to continue, 3) Annual O. mykiss reports by midJanuary the next two years with a summary 2005-2012 fisheries report due by July 1, 2013. For the May 12, 2010 Order: 1) FERC delay resulted in a one year slippage in IFIM data collection, 2) Planned Agency Consultation in August/September, 3) possible Fall Pulse Flow test in October, but most of study expected next year, 4) Water temperature modeling to proceed this year
- Counting Weir: No longer in operation (upper flow limit was found to be $1,300 \mathrm{cfs}$ ). Final 2009 estimate through mid-January was 300 Chinook salmon spawners with 280 counted passing the weir and another estimated 20 downstream of the weir. CDFG carcass survey estimate was 124.
- Screw Trapping: Handouts on catch and size at Waterford and Grayson screw trap sites were reviewed. Catches were characteristically low at Grayson relative to Waterford and mainly only smolts in May; peak catches were associated with turbid conditions in January and March as well as high flows occurring in May as variable spring pulse flows. Some larger salmon from 70-130 mm were also caught in JanFeb.
- Seining size and catch data was reviewed. Peak fry densities occurred in Feb/Mar
with lower densities near the end of the season.
- O. mykiss pop. estimate: Stillwater completed their March survey, with a preliminary report including both the March and July surveys to be completed later this year. If flow conditions allow, an August 2010 survey will be conducted.
- O. mykiss tracking study: Six larger fish have been tagged which have been recorded using the mobile hydrophone within 10 river miles of La Grange Dam.

4. Flow Operations:

- The SJ Basin Index forecast range resulted in a corresponding FERC flow volume requirement of 300,923 AF.
- Don Pedro Reservoir is within 5 ft of capacity and river operations include expected high flows of 2,000-3,000 cfs into July. Discussion of timing a possible 1,300 cfs maximum Fall pulse flow and fall spawning flows of 300 cfs.
- Basin flows and delta CVP/SWP exports graphs were reviewed. Vernalis flows during VAMP were mostly 4,000-6,000 cfs, but exports, which were reduced earlier than before on April 1, increased sharply in late May from 1,500 cfs to 7,000 cfs.

5. Agency/NGO updates

Summary

## 1. Introduction and Announcements

2. AdMINISTRATIVE ITEMS:

- Review/Revise agenda - No changes
- Approve notes from June meeting - No changes were identified. Notes for the last meeting are posted to the TRTAC website: http://tuolumnerivertac.com/
- Items since last meeting - the handout listing the material posted at http://tuolumnerivertac.com/ was reviewed. Those included correspondence regarding the schedules for the IFIM and Water temperature modeling studies included in the May 12, 2010 FERC Order, Draft 2010 Seine report, updated participant list, updates of the basin monitoring newsletter, as well as e-mail correspondences regarding consultation on the planned IFIM study.

3. Monitoring/Reports: Handouts were reviewed

- August reference count and population estimate results: O. mykiss observed from approximately RM 52-39.5 with larger numbers of adult fish than found in the March 2010 surveys or in previous years. A report including both the March 2010 and July 2010 surveys will be done later this year.
- Acoustic tracking Study: Six adult O. mykiss tagged in early 2010 have been tracked using mobile tracking hydrophones, generally remaining within pool habitats in the vicinity of Basso Bridge. 2010-2011 plans include tagging of approximately 20 individuals.
- 2010 Seine report - located on TRTAC website for review.
- Other Summer/Fall monitoring and other study plans: FishBio to resume counting weir operations by September 13, 2010.

4. Flow Operations:

- Reviewed final SJ Basin Index of 3,547,699 AF which corresponds to an AboveNormal Water Year Type with a FERC Flow volume of 300,923 AF. Currently a 6day pulse flow at 800 cfs is planned for October 1-6, 2010. This will be added to the 300 cfs base flow for a total of 800 cfs for the period. This default schedule will be followed unless the three Agencies come to agreement with the Districts on any recommended changes.
- No summer operations related to temperature control were carried out in 2010 due to
high flows and cool air temperatures throughout the Central Valley.

5. Agency/NGO updates

- Tuolumne River Trust to hold annual river cleanup at Legion Park on September 11, 2010
- CDFG expected to expand carcass survey extent downstream of counting weir at RM 24.5

6. ADDITIONAL ITEMS

- None.

7. Next mTg dates - Quarterly on $2^{\mathrm{ND}}$ Thursday: December 9, March 10, 2011

# TECHNICAL ADVISORY COMMITTEE MEETING 

9 December 2010 at 9:30 AM
Turlock Irrigation District, Room 152
Summary

## 1. Introduction and Announcements

- Participants made self introductions.
- There was a brief discussion regarding the upcoming relicensing for the Don Pedro Project. Relicensing will follow the integrated relicensing process (ILP) with the notice of intent (NOI) and preliminary application document (PAD) expected to be filed with FERC in February 2011. A webpage has been established to help interested parties keep abreast of relicensing activities and information. The webpage is at: http://www.donpedro-relicensing.com/default.htm. It can also be found by searching for "Don Pedro Relicensing" on the internet.

## 2. Administrative Items:

- Review/Revise agenda - No changes
- Approve notes from September meeting - No changes were identified. Notes for the last meeting are posted to the TRTAC website: http://tuolumnerivertac.com/
- Items since last meeting - A handout list posted at http://tuolumnerivertac.com/ was reviewed. The list included meeting summaries and notes from the September TRTAC Meeting and IFIM workgroup, correspondences regarding Agency review of the 2010 O. mykiss monitoring and water temperature modeling reports, and 2-D site-selection rationale memorandum. In addition, FERC Progress Reports on the Water Temperature Modeling Study and IFIM studies were posted at the FERC e-Library. Documents include the 2010 O. mykiss monitoring report, the 2010 snorkel survey report, report on the March and August 2010 O. mykiss population size estimates in the lower Tuolumne River, Draft water temperature modeling study report, and IFIM study meso-habitat maps.

3. Monitoring/Reports: (Handouts were reviewed)

- Data posted on the TAC website included updated 2010 thermograph data through September 27, 2010 as well as fall 2010 counting weir data.
- Preliminary run estimates and fish passage on the Tuolumne and Stanislaus River counting weirs were reviewed. Due to high flows resulting from early season runoff, spawner surveys and counting weir operations were halted the week November $30^{\text {th }}$ with a cumulative season total of 766 as of that date. Flows at Modesto were on the order of 3,000 cfs as of December $9^{\text {th }}$ and since flows $<500$ cfs are needed for reinstallation of the weir an unknown number of additional fish may move upstream
without detection. FishBIO estimates that approximately $80 \%$ of the run had passed the weir as of November $30^{\text {th }}$, which would correspond to a season total of just under 1,000 fish.
- Alison and Dave Boucher (TRC) requested continuation of counting operations during spring pulse flows to detect upstream passage of any steelhead arriving in the lower river, subject to the flow limitations of the weir ( $\sim 1,300 \mathrm{cfs}$ ).
- Results of the 2010 O. mykiss population estimate and monitoring summary reports were discussed, including observations of larger fish that may have arrived from upstream. Clarification of flow pathways and durations of bypassed flows will be included in the Final versions of both reports.
- Technical Reports for 2009 FERC Report were distributed as a draft Table of Contents, with a number of reports available on the TRTAC website (seine, snorkel, RST, March/July 2010 Population estimate, and Tracking Study Yr 1 report). Dave Boucher suggested that tracking between June and August would likely represent only resident fish and that location of spawning redds would be extraordinarily difficult as part of this study.
- Alison Boucher and Jesse Roseman (TRT) asked for details regarding the site selection of the 2-D high flow study. Noah Hume (Stillwater) described the site review process and that the Bobcat Flat (RM 43) site was removed from consideration due to planned construction changes in the site topography in 2011. In addition Big Bend (RM 6) and Grayson River Ranch sites (RM 5.5) were removed due to inability to ensure sufficient San Joaquin River flows during Tuolumne River high flow events to provide a hydraulic control and floodplain inundation (backwater effect). Jesse asked questions regarding Tuolumne Flow limitations during flood control releases. Noah will provide Jesse San Joaquin River flow estimates for dates that Big Bend site was found to flood during 2005-2006 monitoring period. Dave described the genesis of the site drainage channels at Grayson and agreed to provide location of portions of the site that may flood at $3,000 \mathrm{cfs}$.
- Other winter monitoring plans: Winter seining surveys, 2-D site surveys, IFIM surveys, and March 2011 snorkel surveys are in preparation.

## 4. Flow Operations:

- Recent flow operations required to maintain flood control storage in Don Pedro Reservoir were discussed. The operational goals during the December/January egg incubation period are to minimize redd scour and rapid dewatering of any redds established during high flows. Current Tuolumne River flows are approximately 3,000 cfs to the lower river, with additional flows of approximately 800 cfs being diverted through the TID canal system and released at the Hickman and Faith Home spills. The MID canal is currently out of service for winter maintenance.

## 5. Agency/NGO Updates

- Tuolumne River Trust: Jesse Roseman summarized TRT activities, including the 2010 Paddle to the Sea fund-raising event, Dos Rios land acquisition, and Dennett Dam draft removal report preparation progress.
- Tuolumne River Coalition: Dave Boucher summarized TRC activities including the site construction plans scheduled at Bobcat Flat (RM 43) during summer 2011. Plans
include floodplain lowering to provide inundation at 3,000 cfs, repair/removal of side channels, construction of point bar complexes, and gravel augmentation. Dave requested that if either IFIM transect surveys or habitat suitability surveys were to result in flows near 100 cfs, the TRC would like to have advance notice to allow coordination of in-channel work activities at Bobcat Flat.

## 6. AddITIONAL ITEMS

- None

7. Next Meeting Dates - (Quarterly on $2^{\text {nd }}$ Thursday at 9:30am)

- 2011 meeting dates: March $10^{\text {th }}$, June $9^{\text {th }}$, September $8^{\text {th }}$, and December $8^{\text {th }}$

# 2010 LOWER TUOLUMNE RIVER ANNUAL REPORT 

Report 2010-1<br>2009 Spawning Survey Report

Prepared by

Tuolumne River Restoration Center La Grange Field Office

## This Page Intentionally Left Blank

The San Joaquin fall-run Chinook salmon is currently a candidate species under Federal and State Endangered Species Acts. Population levels, as measured by escapement of returning adults, in the Tuolumne River declined in the latter half of the $20^{\text {th }}$ century from a high of approximately 130,000 returning adults in 1944 (Fry 1961) to a low of 77 in 1991 (Neilands et al. 1993). Recently, population levels increased to 17,873 in 2000 (Vasques 2001) indicating a slight recovery period, but are once again declining with estimates of 625 in 2006 (Blakeman 2007), 211 in 2007 (Blakeman 2008), and 372 in 2008 (O’Brien. 2009). The decline of the species is believed to be caused by many factors. The reduction of spawning and rearing habitat in combination with stream flow management practices are thought to be the major factors limiting overall population numbers. Numerous additional factors including but are not limited to predation, streambed alteration, pump diversion, gravel mining, land use practices, ocean angler harvest and ocean conditions contribute to a complex web of factors which affect the population dynamics of fall-run Chinook salmon within the Tuolumne River.

The California Department of Fish and Game (CDFG) has conducted escapement surveys on the Tuolumne River since 1953. Mark-Recapture methods have been utilized since 1971 to estimate escapement. Various population models have been used including Schaefer (1951), Jolly-Seber (1973), and the Adjusted Peterson (Ricker 1975). Due to the low number of individuals tagged, the 2009 escapement survey was analyzed using the Adjusted Peterson formula. CDFG escapement surveys have been utilized as part of the New Don Pedro FERC Project No. 2299 license monitoring program and annual reporting.

The primary objectives of the Tuolumne River escapement survey are to:

- Estimate the escapement of fall run Chinook salmon on the Tuolumne River.
- Evaluate the distribution of spawning throughout the study area.
- Collect fork length and sex data.
- Collect and analyze coded wire tag data from hatchery fish.
- Collect tissue samples for genetic analysis.

Collect scale and otolith samples with which to conduct age determination analysis and subsequent cohort analysis.

## General Information

Chinook salmon escapement surveys on the Tuolumne River typically begin around the first week of October and extend into the end of December or early January. The study area is surveyed weekly to monitor the distribution of spawning and to tally the number of carcasses found within the river. Crew members float downstream in a drift boat searching for carcasses, counting live fish and documenting redds in each riffle and subsequent pool. Occasionally, crew members get out of the boat to walk along the sides of the river in search of carcasses that may be too difficult to see from the boat. When a carcass is discovered, it is gaffed out of the water and held on the boat until the entire riffle section (riffle and adjacent downstream pool) has been completely surveyed (Figure 1).

All carcasses found within a riffle section are processed after the area has been adequately searched (Figure 2). "Processing" involves obtaining condition, sex, and forklength (measured in centimeters) data as well as retrieval of scale, ototlith, coded-wire tag, and DNA samples. The survey crew continues floating downstream once all carcasses found within a riffle section have been processed and returned to the tail end of the riffle. The same procedures are followed for each subsequent riffle/pool combination until the entire river section has been completed.

The duration of the survey depends on the availability of new carcasses in the river. Tagging continues until there are less than ten new carcasses found in a survey week. After tagging has ceased, surveys continue for two more "recovery" weeks. Any new carcass found during a recovery week is enumerated, chopped, and returned to the river. Redd and live counts continue during recovery weeks.

## Study Area

Approximately 30.5 river miles were surveyed during the escapement survey in 2009 (Figure 3). The survey area was divided into five sections with Section 1 being the upstream most reach. Section 1, also referred to as the primary spawning reach, extends from riffle A1 at river mile 52.0 near La Grange Dam downstream to Basso Bridge at river mile 47.5. Section 2 extends from Basso Bridge down to the Turlock Lake State Recreation Area (TLSRA) at river mile 41.9. Section 3 extends from TLSRA to riffle S1 at river mile 34. Section 4 extends from riffle S1 downstream to Fox Grove Fishing Access at river mile 26. Section 5 extends from Fox Grove Fishing Access to Santa Fe Rd. at river mile 21.5.

## Riffle Identification

All riffles in the study area have been identified and mapped using a Trimble GPS unit and the GIS computer program ArcView. Each riffle was systematically re-named in 2001 from upstream to downstream using sequential letter/number designations for river mile and riffle number within each river mile, respectively. For example, the first riffle surveyed below La Grange Dam in the first river mile (51) is named A1. The riffle immediately below La Grange Dam (riffle A1) is surveyed by foot and only redd and live fish counts are made. This numbering system is a departure from the historical riffle numbering system; however, the new
riffle identification system is more conducive to editing and tracking riffles as river morphology changes. Changes in riffle locations which may occur during high flow periods, will affect riffle names only within that river mile. There were no changes in riffle names for sections 1-4 from 2008 to 2009 (Table 1). Section 5 riffles were renamed in 2009 using the same sequential letter/number system already being used in sections $1-4$. Figure 4 shows the locations and new names for each riffle within section 5.

## Redd and Live Fish Counts

Weekly redd and live fish counts are conducted during the carcass survey. These counts utilize the riffle identification system noted earlier. Counts are made using tally counters as the field crew floats downstream through each riffle. The single pass method is utilized for conducting redd and live counts. Generally, one person remains responsible for redd counting throughout the entire season. In doing so, there is less variability in the data. Live fish are counted once they swim upstream past the boat in an attempt to prevent double counting.

## Carcass Condition

All carcasses that are that are found within a riffle section (riffle and adjacent downstream pool) are processed after the area has been adequately searched. "Processing" involves obtaining condition, sex, and forklength (measured in centimeters) data as well as retrieval of scale, ototlith, coded-wire tag, and DNA samples.

The condition of each carcass is designated as fresh, decayed, skeleton, or recovery depending on the degree of decomposition or the presence of an aluminum jaw tag in the case of "recoveries". The condition of each carcass dictates how each individual will be processed. "Skeletons" are carcasses judged to be in an advanced state of decay and unlikely to have the same probability of recapture as fresh or decayed specimens (Figure 5). Skeleton condition ranges from a fungus covered carcass to an actual skeleton. Skeletons are enumerated and then chopped in half to avoid double counting before returning to the river. A carcass with at least one clear eye is classified as "fresh" (Figure 6). Fish that have cloudy eyes are considered "decayed" (Figure 7). Fresh and decayed carcasses are tagged and used for sample collection.

## Coded-Wire Tags

Each fresh or decayed carcass is checked for the presence or absence of an adipose fin. Individuals lacking an adipose fin were raised in a hatchery and usually have a metal, codedwire tag (CWT) implanted inside their head. Coded-wire tags are collected and later analyzed as part of survival testing of marked outmigrating smolts. Coded-wire tag returns provide information for determining hatchery contribution rates and can be utilized to analyze the incidence of straying from other river systems. Coded-wire tag data is also being used to validate scale and otolith age determination work.

Survey crews remove the upper portion of the heads of CWT carcasses while working on the river. The lower jaw of the carcass remains attached to the rest of the body so that a metal "field tag" can still be attached. Once the head has been removed, it is placed in a labeled "head bag" and catalogued by the unique jaw tag number so that it can be tracked to the specific date and riffle number of collection. Extraction and analysis of CWT's is conducted at the La Grange field office after the spawning season has concluded.

## Tissue Collection

Scale, otolith, and DNA samples are taken from as many carcasses as possible. Generally, otolith samples can be obtained from most carcasses, but some individuals may be too badly decomposed to collect DNA and scale samples. All samples are catalogued by the unique jaw tag number which allows the samples to be tracked to the specific date and riffle of collection. Samples are collected from both wild and CWT carcasses and are catalogued, stored, and analyzed at the CDFG La Grange Field Office (Figures 8 and 9).

## Otolith Samples

Otoliths are extracted from each carcass found on the river. A horizontal incision is made above the eyes and nostrils towards the posterior end of the fish ending slightly above the gill cover. The incision is made so that the top of the head can be removed and the brain capsule exposed. A pair of tweezers are used to reach inside and extract the otoliths which are the only hard structures found within the capsule (Figure 10). Any adhering tissue is removed from each otolith before placing the pair inside an individual vial marked with the field tag number.

## DNA Fin Clip and Scale Samples

DNA fin clip samples are taken from the "meaty" region of the pectoral fin. The sample size is between $15-20 \mathrm{~mm}$ long and $5-10 \mathrm{~mm}$ wide. The samples are dried for at least 48 hours upon arrival to the lab. Scales are collected to determine the size and age composition of annual spawning runs. Scale samples are obtained by using a knife to scrape in a back and forth motion along the side of the carcass. (Scales near the lateral line are avoided) Approximately twenty or more scales are collected from each carcass.

## Assignment of Unique Identification Number

Each carcass, with the exception of skeletons, is assigned a unique identification number by affixing a metal, numbered tag to the bottom jaw (Figure 11). This number identifies each individual throughout the season so that it can be identified if found again at a later date. Tags are issued in sequential order throughout the season. Newly processed carcasses are redistributed to moving water in the tail end of the riffle, above the pool from which they were collected, for recovery in subsequent weeks.

## Tag Recoveries

Previously tagged carcasses are considered "recoveries" if they are found again during a survey subsequent to the tag week. Each recovery tag number is recorded by the unique tag number before returning the carcass back into the water at the bottom end of the riffle. Recovery totals are essential in calculating annual population estimates because they determine the overall success rate of the field crew's ability to locate carcasses in the river.

In past years’ escapement surveys, previously tagged carcasses were chopped in half upon recovery to prevent multiple recaptures. Since 2008, tagged carcasses were recovered as many times as they were found, and returned to the water in tact each time. This new technique is being utilized to determine the longevity of carcass retention within the river system. Multiple recapture data is not currently being utilized in the data analysis for determining the population estimate.

## Data Management/Analysis

Datasheets are reviewed by a data entry technician prior to being entered into a Microsoft Access database. All newly entered data goes through a quality control process in which a second individual prints out line-by-lines to check for any data entry errors. The biologist receives a copy of the database after all data entry errors have been corrected. Microsoft Excel is the current program being utilized for data analysis. Escapement reports generate annual population estimates but also analyze other factors such as population composition, egg production estimates, and distribution of spawning within the river.

CDFG has used a variety of population models since escapement surveys began in 1953. This year, the Adjusted Peterson equation was used in calculating the population estimate due to low numbers of Chinook salmon being marked. Carcasses are marked and subsequently recovered during weekly surveys of the spawning reach. A ratio of recoveries to the total tagged available is used to calculate an estimate of the total spawning population. Total fish handled includes total fish tagged, skeletons, and recoveries by week.

The Adjusted Peterson equation was used in generating two separate population estimates for the 2009 Tuolumne River carcass survey. Sections $1-4$ were surveyed between October 5, 2009 (week 1) and January 13, 2010 (week 15). A section 1-4 estimate was calculated to represent the approximately 25 mile stretch of river located upstream of the newly constructed Tuolumne Weir. An additional estimate was calculated separately to determine the population of fish spawning downstream of the weir in section 5 . Section 5 was surveyed between November 4, 2009 (week 5) and January 6, 2010 (week 14).

Carcasses were tagged for the first 13 weeks of the survey. The final 2 weeks were considered recovery weeks. The three carcasses encountered during weeks 14 and 15 in section one were processed to obtain sex, forklength, condition, and CWT data. DNA, scale, and otolith samples were also taken; however, these three individuals were treated as skeletons in the population estimate.

The Adjusted Peterson equation:

$$
N=\frac{(M+1)(C+1)}{R+1}
$$

Where:
$\mathrm{N}=$ Population estimate
M=Number of carcasses tagged
C=Catch (total number of tagged and skeletons)
$\mathrm{R}=$ =Number of recoveries

An Alaskan weir began operation on the Tuolumne River on September 22, 2009 as a method for counting migrating salmonids (Figure 12). This was the first time a weir had been operated on the Tuolumne; however, a similar weir had been in use on the Stanislaus River since 2003. The Tuolumne weir is owned by Turlock Irrigation District but operated by the consultant company Fishbio. The placement of the weir was intended to be in a location well downstream of any potential spawning habitat. The weir was constructed at river mile 24.5 approximately 1.7 miles downstream of Geer Rd. ( $37^{\circ} 37^{\prime} 43.44^{\prime \prime} \mathrm{N} \quad 120^{\circ} 51^{\prime} 42.48^{\prime \prime} \mathrm{W}$ ) where the substrate consists primarily of sand, mixed with small gravel.

On October $30^{\text {th }}$, 2009 CDFG biologists’ conducted an informal survey below Geer rd. to assess possible spawning activity downstream of the newly constructed Tuolumne weir. The discovery of approximately 25 live salmon and one redd within one mile downstream of the weir led to the inclusion of section 5 in the carcass survey in subsequent weeks.

Spawning activity appeared to have increased downstream of the weir when formal carcass surveys began in section 5 on November $4^{\text {th }}$ (week 5). A total of 5 redds were documented within one mile downstream of the weir as compared to a total of 8 redds that had been observed in the entire 26.5 mile stretch upstream of the weir during the same week. During week 5 of the escapement survey approximately $38 \%$ of the total observed spawning activity and $34 \%$ of the total live fish observations for the entire river occurred downstream of the weir.

Week 6 survey data continued to show that migrating salmon were likely being subject to a passage delay at the weir. Redd counts continued to rise, with approximately $25 \%$ of the total observed spawning activity occurring downstream of the weir. Approximately $25 \%$ of the total live fish observations were also observed downstream of the weir during week 6 . The discovery of a decayed female carcass within 1.15 miles downstream of the weir on November $12^{\text {th }}$, increased DFG's concern that the weir was affecting fish passage.

By week 7 of the escapement survey, it was clearly obvious that a significant number of fish were unable to move upstream past the weir and as a result, were spawning in poor habitat that they would likely not otherwise choose. Live fish continued to be observed in close proximity to the weir, with some individuals choosing to spawn directly underneath the weir panels. An additional 3 carcasses were discovered downstream of the weir during the November $20^{\text {th }}$ survey. In addition, redd counts downstream of the weir continued to rise to a total of 14 .

On the morning of November $20^{\text {th }}$, Fishbio began removing three weir panels to allow unobstructed fish passage past the weir as directed by the Department of Fish and Game (Figure 13). A temporary video monitoring system was setup to attempt to monitor the gap in the weir. CDFG biologists' reassessed the situation two days later to determine if the panels could be reinstalled. Survey data collected November $22^{\text {nd }}$ indicated an increase in spawning below the weir thus making it necessary to postpone reinstallation of the three panels. After ten days of unobstructed fish passage, Fishbio was permitted to reinstall the weir panels on November $30^{\text {th }}$.

The Tuolumne weir appeared to have had a significant impact on migrating salmon in 2009. During the 15 weeks of the escapement survey, a total of 15 carcasses (tagged and skeleton) were found within 2 miles downstream of the weir, as compared to a total of 40 that were discovered for the entire 26.5 mile stretch upstream of the weir The inability of fish to move upstream to desirable spawning grounds was unacceptable especially with the current trend of critically low annual escapement numbers.

The Department of Fish and Game addressed its concerns regarding the design and location of the Tuolumne weir after the conclusion of the carcass survey. Modifications to the weir design will be made prior to being placed back in the water for the 2010 season.

## 4 RESULTS

## Survey Duration

The 2009 Tuolumne River carcass survey was conducted between October 5, 2009 and January 13, 2010. Drift boat surveys were conducted weekly between the La Grange Dam and Fox Grove fishing access (sections 1-4) for the entire 15 weeks of the survey. Section 5 was included in the carcass survey beginning in week five in response to spawning activity occurring downstream of the weir. Carcass surveys within section 5 were conducted weekly between November 4, 2009 and January 6, 2010.

## Escapement Estimate

Sections 1-4 were surveyed for 15 weeks between October 5, 2009 and January 13, 2010. Section 5 was surveyed for 10 weeks between November 4, 2009 and January 6, 2010. It was necessary to generate two separate Adjusted Peterson estimates in 2009, due to the fact that the stretch of river located upstream of the weir (sections 1-4) was surveyed longer than the stretch of river located downstream of the weir (section 5). The generation of two separate estimates also demonstrates the population of fish that were possibly delayed by the weir, and as a result spawned in poor substrate conditions in section 5 .

## Section 1-4 Escapement Estimate

A total of 24 carcasses were tagged in sections 1-4 during the 2009 Tuolumne River escapement survey. An additional 16 skeletons were tallied and chopped, giving a total of 40 individual Chinook salmon handled in sections 1-4. There were no live fish counted in sections 1-4 during week 15 of the survey. The overall recovery rate for sections $1-4$ was $52.38 \%$. The Adjusted Peterson model utilizes the number of recoveries of tagged carcasses, the total number of tagged fish, and the total number of carcasses handled to generate an escapement estimate. Based on the Adjusted Peterson model, the 2009 escapement estimate for sections 1-4 was 75 salmon.

## Section 5 Escapement Estimate

A total of 13 carcasses were tagged in section 5 during the 2009 Tuolumne River escapement survey. An additional 2 skeletons were tallied and chopped, giving a total of 15 individual Chinook salmon handled in section 5 . There were no live fish counted in section 5 during week 14 of the escapement survey. The overall recovery rate for section 5 was $38.46 \%$. The Adjusted Peterson model utilizes the number of recoveries of tagged carcasses, the total
number of tagged fish, and the total number of carcasses handled to generate an escapement estimate. Based on the Adjusted Peterson model, the 2009 escapement estimate for section 5 was 37 salmon.

The estimate of 75 salmon for sections 1-4 and the estimate of 37 salmon in section 5 resulted in a total population of 112 salmon for the Tuolumne River in 2009. Table 2 and figure 14 show historical Tuolumne River escapement estimates from 1978 to 2009. The overall recovery rate for sections $1-5$ was $45.42 \%$. Females and males accounted for $56.8 \%$ and $43.2 \%$ respectively of the total tagged fish on the Tuolumne River. Table 3 shows tagged, skeleton, recovery, and CWT weekly totals.

## Live Salmon and Redd Counts

Live fish observation peaked at week 8, and demonstrated an overall declining trend throughout the remainder of the survey. Redd counts peaked in week 8 with a maximum of 74 redds counted and then steadily declined for the remainder of the study period. Total carcass counts peaked in week 10, at 10 (Table 4 and Figure 15). The maximum number of redds counted for individual riffles is presented in Table 5.

## Distribution of Spawning

The distribution of spawning in 2009 showed changes from the typical spawning patterns observed on the Tuolumne River in prior years’ escapement surveys. Typically, spawning activity tends to be highest at the upstream most reach of the river in section one. Section 3 tends to have the next highest spawning activity, followed by section 2. Minimal spawning generally occurs in section 4 as compared to the upper sections.

The 2009 spawning distribution did not show the typical trend of the highest spawning activity being associated with section 1 . Minimal spawning activity occurred in section one, with a maximum weekly redd count of just 32 (Figure 16). The highest maximum weekly redd count was observed in section 5, with the majority of spawning occurring within 1.5 miles downstream of the Tuolumne weir. The maximum weekly redd count for section 5 was 40. Sections 2, 3, and 4 had maximum weekly redd counts of 20,36 , and 10 respectively. Figure 17 show weekly maximum redds observed by river mile.

## Population Composition

The total composition (tagged fish only) for fall-run Chinook salmon in the Tuolumne River was $54.1 \%$ natural females, $35.1 \%$ natural males, $2.7 \%$ CWT females, and $8.1 \%$ CWT males (Figure 18). Table 6 shows the yearly percent composition of fall-run Chinook salmon on the Tuolumne River since 1992. Coded wire tagged fish comprised approximately $11 \%$ of the total tagged carcasses. Skeletons were not checked for adipose fin clips due to their advanced state of decomposition; however, it is likely that ratios calculated for tagged fish are representative for skeletons as well. Table 7 shows the tag code, brood year, release year, and release location for all CWT fish collected in the Tuolumne River in 2009.

Twenty one females were tagged in 2009, with forklengths ranging between 54 cm and 90 cm . The average female forklength was 76.8 cm . The sixteen males that were tagged in 2009 had forklengths ranging between 52 cm and 110 cm . The average forklength for all males tagged
was 70.1 cm . Figure 19 shows a length frequency histogram for all Chinook salmon tagged in 2009. Total grilse composition was $29.7 \%$ of all examined fish. Breakpoints between grilse and adult were determined from basin wide fork length data and applied to Tuolumne River fork length data to determine grilse composition. The breakpoints used in 2009 were $<63 \mathrm{~cm}$ for females and $<70 \mathrm{~cm}$ for males. Eight males were considered grilse based on fork lengths less than 70 cm . Three females had fork lengths of 62 cm or less and were also considered grilse.

## Scale, Otolith, and DNA Collection

Scale and otolith samples were collected from all tagged carcasses. DNA was also taken from most tagged carcasses; however, several individuals were too badly decomposed to retrieve adequate DNA samples (Tables 8, 9 and 10). Samples were not collected from skeletons due to the advanced state of decomposition. Scale and otolith samples will be utilized in the CDFG age determination program and for subsequent cohort analysis of the San Joaquin River Basin Chinook salmon populations. This data will also be essential for population models being developed as well as ongoing cohort analysis of factors affecting the populations.

## Egg Production Estimation

An estimate for the number of eggs produced by the 2009 fall-run was generated using a standard regression equation (158.45 * fork length cm -6138.91 = number of eggs). This fork length-fecundity relationship was determined for 48 San Joaquin fall-run Chinook salmon females ranging from 62.5 to 94.0 cm fork length (Loudermilk et al. 1990). The number of eggs was calculated for all females (CWT and natural) and expanded by the ratio method. The average fork length for all females in 2009 was 76.8 cm . An estimated 379,672 eggs were produced by natural and CWT female Chinook in 2009. CWT females were estimated to have produced 16,802 eggs. Natural females were estimated to have produced 362,870 eggs.

## Tuolumne River Flows

The Tuolumne River flows, recorded at the La Grange gauge, for the period of October 1, 2009 through January 17, 20010 are shown in figure 20 (preliminary data obtained from the California Data Exchange Center). A pulse flow was released during the period between October 11th and October $23^{\text {rd }}$ with a maximum flow of 716 cfs on October 18th. The average daily flow between October 1, 2009 and January 17, 2010 was 286 cfs.

## Tuolumne River Temperature

Water temperature on the Tuolumne River is recorded using onset temperature monitors at twelve different locations starting below the La Grange powerhouse and ending downstream below the Hickman spillway. Figure 21 shows Tuolumne River water temperatures recorded at riffle C1 and at the above Hickman spillway sites. These water temperatures are plotted verses flow, maximum thermal limit for successful egg incubation, and live fish/redd counts.

## Multiple Recaptures

In past years' escapement surveys, tagged carcasses were chopped in half upon recovery to prevent multiple recaptures. Since 2008, tagged carcasses were recovered as many times as they were found, and returned to the water in tact each time. This new technique is being utilized to determine the longevity of carcass retention within the river system. Of the
seventeen carcasses that were recovered during the 2009 survey, eleven were recovered only one time, three were recovered twice, and three were recovered three times (Figure 22). Multiple recapture data was not used in the data analysis for determining the population estimate, as the low number of fish handled would not allow the use of models that incorporate that data.

## Spring/Summertime Live Fish and Carcasses

The Department of Fish and Game does not conduct carcass surveys on the Tuolumne River in spring and summer months however, live fish and carcasses have been observed on the river by CDFG during these times of year. The following list documents the timing of these observations in 2009.

1) February 18, 2009
2) February 22, 2009
3) February 23, 2009
4) March 11, 2009

Seven live fish, 5 redds, two non-adclip carcasses, and two skeletons were found between the La Grange powerhouse and Bassos bridge.

Two live fish and one redd were observed in riffle H4 (RM 44.6)
One live fish and one redd were observed in riffle T2 (RM 32.5) near Waterford.

Six live fish and one skeleton were documented upstream of Hwy J59.
5) March 23, 2009 Two live fish were observed near riffle A2 (RM 51.6).
6) April 22, 2009
7) July 15, 2009

## 5 DISCUSSION

The 2009 escapement estimate of 112 and 2007’s estimate of 211 are the lowest numbers of Chinook returning to the Tuolumne River since the 1991 estimate of 77 adults (Table 2 and Figure 14). Populations of Chinook have been in decline throughout the San Joaquin River system with similar low population trends also occurring on the Stanislaus and Merced Rivers.

The Jolly-Seber model would be a better estimation if tagged and recovered fish were more than 10 for each survey week (Schwarz 1993, p. 1183). In the 2009 Tuolumne River Escapement Survey, both tagged and recovered fish were low. During the 15 weeks of the survey, there were never more than 10 carcasses tagged or recovered in any single week. The Schaefer model overestimates when tagged and recovery are both low (Law 1994). Due to
very low numbers, the Adjusted Peterson method was used to calculate the 2009 escapement estimate of 112 returning adults.
Stream flow dynamics affect the likelihood of collecting carcasses in that it effects both how carcasses are distributed in the system and the effectiveness of recovering carcasses by field crews. The overall recovery rate of $45.42 \%$ for sections $1-5$ indicates the percentage of carcasses that were recovered at least one time within the river. Since 2008, tagged carcasses were recovered as many times as they were found, and returned to the water in tact each time to determine the longevity of carcass retention within the river system.

Redd counts are affected by time of day, visibility, sunlight, wind rippling the water surface, redd superimposition, and other physical factors as well as the natural variability between observers. Redd counts were conducted with a single pass as opposed to a more complete intensive systematic approach which is beyond the scope of current funding. Maximum weekly redd distribution of section one to section five was $23.2 \%, 14.5 \%, 26.1 \%, 7.2 \%$ and $29.0 \%$ of total observed redds. The Tuolumne weir appeared to have negatively impacted migrating salmon, thus resulting in a large proportion of fish spawning downstream of the weir in poor substrate conditions. With so few fish returning to spawn there was likely very little redd superimposition occurring in 2009

There were four CWT fish encountered during the escapement survey in 2009. Skeletons were not checked for adipose fin clips due to their advanced state of decomposition. Females made up $56.8 \%$ of the returning adult population. The percentage of males returning to the Tuolumne in 2009 was $43.2 \%$. The fork lengths of all salmon examined in the San Joaquin River Basin was utilized in determining grilse breakpoints. Eight males were considered grilse based on fork lengths less than 70 cm . Three females had fork lengths of 62 cm or less and were also considered grilse. The total percentage of grilse examined in the Tuolumne River was 29.7\% of all examined fish.

The 2009 escapement estimate of 112 individuals causes great concern about the future survival of Chinook salmon in the Tuolumne River. There are many unanswered questions as to why the once healthy population has dropped to such dramatically low numbers. At this point, there is no definitive answer as to the cause of the Chinook population decline. A complex web of factors including flow management practices, predation, reduction of spawning and rearing habitat, streambed alteration, pump diversion, gravel mining, land use practices, ocean angler harvest and poor ocean conditions affect the population dynamics of Chinook salmon in the Tuolumne River.

# SPAWNING SURVEY SUMMARY UPDATE 

## 1. INTRODUCTION

The California Department of Fish and Game (CDFG) has conducted fall-run Chinook salmon spawning surveys on the Tuolumne River since 1971 as part of the fish study program for the Don Pedro Project FERC license. TID/MID 1992 reviewed the 1971-1988 period and TID/MID 1997 summarized the 1989-1996 period. This report updates Ford and Kirihara 2009 and summarizes the 1971-2010 period. This report contains the latest information provided by CDFG for both 2009 and 2010.

## 2. SUMMARY UPDATE

### 2.1 Survey Reach

The reach CDFG surveyed in 2009 and 2010 was extended downstream into Section 5 (Figure 1) that starts near Fox Grove (RM 26.4) and extends to Santa Fe Br. (RM 21.5). Our records indicate that reach has not been reported as surveyed for spawning activity by CDFG since about 1989. The survey was extended downstream to examine for spawning activity above and below the Tuolumne River counting weir (RM 24.5), but there is little comparable data available due to the lack of surveys in prior years.

### 2.2 Population Estimates, Sex Composition, and Potential Eggs

Tuolumne River carcass numbers, mark/recapture survey results, and population estimates since 1971 are in Table 1. Those 2009 carcass data do not include Section 5 where CDFG reported an additional 15 total carcasses, including 13 tagged and 7 recovered in that mark/recapture effort. The 2009 run estimate of 300 is based on 280 counted at the Tuolumne weir through Jan 15 and 20 more salmon estimated below the weir (Figure 2). The 2010 run estimate of 766 was also taken from the weir counts which ended early, on 30 Nov., due to high flows. The initial CDFG estimates based on carcasses surveys were 112 and 540 for 2009 and 2010, respectively. The 2010 estimates (both weir count and CDFG survey) do not account for salmon spawning after November. The Tuolumne salmon run estimates for 1971-2010 have ranged from less than 100 salmon in 1990 and 1991 to 40,300 fish in 1985. Detailed and specific data on previous year's surveys can be found in past annual reports submitted to FERC. Estimates for the San Joaquin basin rivers since 1940 are in Table 2. All estimates in this summary update report for 2009 and 2010 Tuolumne River fall Chinook salmon are based on calculations utilizing the weir count numbers and may differ from numbers contained in the CDFG annual report (2009).

The percentage of females in the 1971-2010 runs has ranged from $25 \%$ in 1983 to $67 \%$ in 1978 (Figure 3). The years with less than $40 \%$ females usually had runs containing a large percentage of 2 -year-old males. In 2009 there were about $57 \%$ females in the run and in 2010 there were about $34 \%$ based on all measured carcasses.

Beginning in 1981, the potential egg deposition for each year has been estimated using the number and average size of females. This is based on a formula from CDFG Los Banos trap data collected in 1988 using a female size to egg number relationship. These potential egg deposition estimates
have ranged from 145,000 in 1991 to 128.6 million in 1985 (Figure 4, Table 3). The estimated 2009 potential egg number was about 1.03 million based on approximately 170 females with an average fork length of 76.8 cm . In 2010 the estimated potential egg number was about 1.47 million based on approximately 258 females with an average fork length of 74.6 cm .

### 2.3 Live and redd counts

Table 1 has the maximum weekly counts of live salmon and redds from the CDFG surveys. The earliest date of peak weekly live count for the 1971-2010 period was Oct 31, 1996 and the latest peak was Nov 27, 1972 with a median date of Nov 12 (Table 4). The 2010 run had a peak live count of 142 salmon during the week of Nov 01 . During the week of Nov 15 , the peak redd count of 105 occurred.

### 2.4 Length Frequency Distribution and Age Class Composition

Fork length measurements have been recorded for carcasses since 1981. Males are typically longer than females of the same age. Generally, the average length of all males is longer than of all females with the exception of years that have a high proportion of 2-year-olds, which are mostly males (Figure 5, Table 5). Estimation of age-class composition based on visual examination of the length frequency distribution of fresh measured carcasses was made for the 1981-2010 surveys (Table 6). These initial estimates are made for comparative purposes and may be modified when age analysis of scale/otolith samples and lengths of known age hatchery fish is utilized. The estimated female maximum fork lengths for ages two, three, and four were typically about 65,83 , and 95 cm respectively. Male fork length maximums for ages two, three, and four were 70, 90-95, and 105 cm , respectively. The most notable exceptions to the age/length estimates occurred in 1983-1984 and 1997-2000 when ocean growth of salmon may have been reduced due to El Niño (warm water) conditions that affected food resources.

Runs are mainly dominated by either 2 or 3-year-old salmon as shown in Figure 6. The 1998, 1999, and 2004 runs were estimated to have fairly equal numbers of two and three-year-old salmon. The 2009 and 2010 runs were dominated by 3 -year-old salmon. Four-year-olds were estimated to be the most abundant age class only in 2001, but were estimated to be more than $10 \%$ of the 1986, 1989, 1990, and 1997-2009 runs. 2001 and 2007 had the highest estimated percentage of four-year-old salmon in the 1981-2010 study period. Five-year-olds are estimated to have comprised from $0-8 \%$ of the runs.

### 2.5 Linear Regression Analysis of 2-year old salmon vs. following year 3-year olds

A linear regression analysis of the logarithmic values for all estimated 2-year old salmon and the following year estimated 3 -year olds resulted in an $r^{2}=.82$ for the 1981-2009 period (excluding the 1984 outlier). A similar analysis for estimated 2-year old female salmon only and the following year estimated 3 -year old females resulted in an $r^{2}=.78$ (Figure 7). These analyses indicate a high degree of correlation for both all 2-year old salmon and for 2-year old females returning the following year as 3 -year olds of that brood year.

### 2.6 Estimated Cohort Returns

The number of returns from a given cohort (spawning run) to the Tuolumne River was estimated using the age class composition values previously described. This enables cohort return estimates from the 1979 run, which first returned as 2 -year olds in 1981 ; up to the 2007 run with 3 -year olds returning in 2010 (the 2007 cohort was almost complete with 4 -year olds still to return in the 2011 run). Runs since 1987 have had higher percentage contributions of known hatchery origin fish but no attempt was made here to separately consider their influence on the cohort returns.

The cohort return for a given year was determined by adding the estimated age 2 through age 5 returning fish from the subsequent runs. For example, the 1979 spawning run cohort returned as 2year olds in 1981, 3-year olds in 1982, 4-year olds in 1983, and 5-year olds in 1984. Table 7 contains the age-class percentage estimates for each run, the corresponding number estimates that were added to result in the estimated cohort returns, and the estimated age composition of the cohorts. Figure 8 depicts the estimated runs with their estimated cohort returns, showing a wide range of variability.

### 2.7 Coded wire tagged hatchery salmon

The 2009 run contained 4 coded wire tag (CWT) salmon that originated from the Mokelumne River Hatchery and were released at several bay area locations. The 2010 run contained 27 possible CWT's out of 86 measured salmon but the tags have not been read yet. This high percentage of hatchery origin salmon might indicate that a high degree of straying is occurring from these releases.

# 2010 LOWER TUOLUMNE RIVER ANNUAL REPORT 

Report 2010-3
2010 Seine Report and Summary Update

Prepared by

Tim Ford
Turlock and Modesto Irrigation Districts
and
Steve Kirihara
Stillwater Sciences
Berkeley, CA

## EXECUTIVE SUMMARY

The 2010 seining survey was conducted at two-week intervals from 26 January to 08 June for a total of 10 sample periods. This was the 25th consecutive annual seining study on the Tuolumne River conducted by the Turlock and Modesto Irrigation Districts.

A total of 386 natural Chinook salmon were caught in the Tuolumne River and none in the San Joaquin River. This was the $7^{\text {th }}$ lowest number of salmon caught during the 1986-2010 period and salmon were captured downstream to the Charles Rd. location (RM 24.9). Peak density of salmon caught in the Tuolumne was 7.8 salmon per 1,000 square feet on 02 March. Maximum fork length (FL) in the Tuolumne River increased from 47 mm FL to 88 mm FL from 26 January to 30 March and minimum FL was 29 mm .

Flows during the sampling period ranged from about 220 to 3,300 cubic feet per second (cfs) in the Tuolumne River at La Grange and from about 1,200 to 6,000 cfs in the San Joaquin River at Vernalis. Flows in 2010 increased significantly beginning in early April due to above average precipitation.

Water temperature in the Tuolumne ranged from $10.1^{\circ} \mathrm{C}$ to $18.4^{\circ} \mathrm{C}$ and in the San Joaquin from $9.4^{\circ} \mathrm{C}$ to $25.8^{\circ} \mathrm{C}$. Conductivity in the Tuolumne River ranged from 27 to $205 \mu \mathrm{~S}$ and in the San Joaquin from 211 to $1,406 \mu \mathrm{~S}$.

A comparative review of fork length and salmon density for the 2005-2010 period is included. Increase in average fork length in 2010 was typical in timing and magnitude to the pattern observed in other years through early April. After that, average fork length remained fairly stable due to low catch numbers and the outmigration of smolts.

Density of fry ( $\leq 50 \mathrm{~mm}$ ) peaked on 17 February, similar in timing to other years of the 2005-2010 period. The density of juveniles (>50 mm) peaked on 30 March, which was also similar to other years in the period. In 2010, the average density of salmon in the Tuolumne River was 2.9 salmon per $1,000 \mathrm{ft}^{2}$, most similar to 1997 .

## 1 INTRODUCTION

Stillwater Sciences with assistance from FISHBIO conducted seine studies in the Tuolumne and San Joaquin Rivers in 2010 for the Turlock and Modesto Irrigation Districts (TID/MID).

Seine sampling was done in both rivers pursuant to the Don Pedro Project river-wide monitoring program. A primary objective was to document juvenile salmonid size, abundance and distribution, including the relationship of flow and other environmental variables. The salmon in 2010 were the progeny of the 2009 fall spawning run, estimated at about 300 fish counted at the Tuolumne River weir. This was the 25th consecutive annual TID/MID seining study and a summary of salmonid data since 1986 is contained in this report.

### 1.1 STUDY SITES

The area studied was the Tuolumne River from La Grange Dam (river mile [RM] 52.0) to its confluence (RM 0) with the San Joaquin River at RM 83.8, and the San Joaquin River from Laird Park (RM 90.2) to Gardner Cove (RM 79.4) (Fig. 1). A total of ten sites were sampled each survey period, eight on the Tuolumne and two on the San Joaquin. The locations of the sites were as follows:

a. From the confluence with the San Joaquin River.
b. From the confluence with the Sacramento River.

The Tuolumne River was stratified into three sections. The upper section (RM 52 to 34), sites 13 , is a higher gradient area that includes most of the primary spawning riffles in the river. The middle section (RM 34 to 17), sites $4-6$, is the transitional area from the gravel-bedded to sandbedded river reaches. This section contains much of the in-channel sand/gravel mined areas. The lower section (RM 17 to 0 ), sites $7-8$, is a lower gradient, mostly sand-bottom reach downstream of the Dry Creek confluence.

### 1.22010 TUOLUMNE AND SAN JOAQUIN RIVER SAMPLING CONDITIONS

Flows released in the Tuolumne River below La Grange Dam were approximately 220 cfs in January when the surveys began. Several winter rain runoff events occurred from late January to early March as was evident in flows at Modesto. Releases began increasing in early April due to above average precipitation in the watershed (Fig. 2). During April and May, there were several pulse flows of about 3,300 cfs. In mid-June flows increased to a high of 5,520 cfs .

Flows in the San Joaquin River at Vernalis (RM 72.5) ranged from 1,200-6,000 cfs from January through June.

Flows upstream of Vernalis, at Patterson Bridge (RM 98.5) and Maze Road (RM 77.3), represent flow levels at the sampling locations of Laird Park upstream of the Tuolumne and Gardner Cove downstream of the Tuolumne, respectively.

The minimum water temperature recorded in the Tuolumne River during the study period, based on hand-held temperature measurements, was $10.1^{\circ} \mathrm{C}\left(50.2^{\circ} \mathrm{F}\right)$ at Shiloh Rd on 26 January and at OLGB on 16 March, and the maximum temperature was $18.4^{\circ} \mathrm{C}\left(65.1^{\circ} \mathrm{F}\right)$ at Shiloh Road on 30 March (Fig. 3). The lowest San Joaquin River water temperature, $9.4^{\circ} \mathrm{C}\left(48.9^{\circ} \mathrm{F}\right)$ was at Laird Park on 26 January; the highest was $25.8^{\circ} \mathrm{C}\left(78.4^{\circ} \mathrm{F}\right)$ at Laird Park on 08 June.

Dissolved oxygen concentration in the Tuolumne River ranged from 8.6 to $15.2 \mathrm{mg} / \mathrm{L}$ (ppm) and from 8.3 to $14.3 \mathrm{mg} / \mathrm{L}$ in the San Joaquin River (Fig. 3).

## 2 METHODS

### 2.1 STUDY TIMING

The 2010 seining study began on 26 January and ended on 08 June. Sampling was done at twoweek intervals, with a total of 10 sampling dates.

### 2.2 SAMPLING METHODS AND DATA RECORDING

Seining was done using a 4 -ft high, $1 / 8$-inch mesh nylon seine net 20 feet in length. The same general areas were sampled each time, to permit comparisons through the sampling period, but sample areas varied somewhat as a result of changes in flow, especially after early April. Seine hauls were made with the current and parallel to shore. The salmon caught were anesthetized with MS-222, measured (FL in mm ) and then revived before being released. Other measurements taken were area sampled, (determined from estimating average length and width of a seine haul) water temperature, visibility, conductivity, turbidity, dissolved oxygen, and maximum depth of the area sampled. Other observations include time of day, weather conditions, habitat type, and substrate type. Other fish species were recorded separately. Any salmon undergoing outward signs of smoltification, such as losing scales during handling, were also noted.

### 2.3 DATA ANALYSIS

Seining catch data was examined by location, river section, and river. Catch densities of salmon were divided into two size groups for analysis. The density index for "fry" (fish $\leq 50 \mathrm{~mm}$ FL) and for "juveniles" ( $>50 \mathrm{~mm}$ ), by site and by section, were computed by multiplying the number of salmon caught by 1,000 and dividing it by the area sampled. These indices of population density (relative abundance), were used for comparisons. Densities and sizes of salmon fry and juveniles by upper, middle, and lower river sections were examined.

## 3 RESULTS AND DISCUSSION

### 3.1 SEINE CATCH

A total of 386 salmon were caught in the Tuolumne River and 0 in the San Joaquin (Table 1). All salmon were measured and riverwide peak density for the Tuolumne was 7.8 salmon per $1,000 \mathrm{ft}^{2}$ on 02 March. Peak density is normally observed in mid to late February.

### 3.1.1 Density of Fry and Juvenile Salmon

Salmon up to 47 mm fork length (FL) were caught in the Tuolumne River on 26 January. The highest density of salmon fry in the Tuolumne was 6.1 fry $/ 1,000 \mathrm{ft}^{2}$ found on 17 February (Table 2). The highest density of juvenile salmon in the Tuolumne was 3.6 juveniles $/ 1,000 \mathrm{ft}^{2}$ found on 30 March.

The density of salmon fry exhibited a peak at all sites from 17 February to 02 March. The density of juveniles generally peaked from 02 March to 13 April for all locations (Fig. 4).

The density of salmon fry in the Tuolumne River peaked in the upper section on 17 February, in the middle section on 02 March and none were caught in the lower section (Fig. 5).

The density of juveniles peaked in the upper section on 13 April, the middle section on 30 March and again, none were caught in the lower section. No salmon were caught in the San Joaquin River.

### 3.1.2 Size, Growth, and Smoltification

The fork length of salmon caught ranged from 29 mm to 101 mm . The average fork length (FL) of salmon generally increased from 26 January to 13 April (Fig. 6). An indirect method to estimate growth rate was made by dividing the increase in maximum FL, over a period of time. Maximum FL in the Tuolumne River increased from 47 to 88 mm during the 26 January to 30 March period (Fig. 6), indicating a potential FL increase of approximately .65 mm per day ( 41 mm / 63 days).

Length frequency distributions by survey period are in Figs. $7 \& 8$. The change in FL by location generally shows an increase from late January to late April at most of the Tuolumne River sampling locations (Fig. 9). The first salmon exhibiting smolting characteristics were
caught on 16 March with the exception of a 101 mm FL salmon caught on 17 February. For the year, smolting salmon ranged from 55-101 mm FL. Fry were present through 08 June during the 2010 seine survey period.

### 3.1.3 Conductivity and Turbidity

Conductivity in the Tuolumne River generally increased with increasing distance below La Grange Dam, from a low of $27 \mu \mathrm{~S}$ at OLGB to a high of $205 \mu \mathrm{~S}$ at Shiloh Road (Table 3). Conductivity also decreased as flows increased beginning in April (Fig. 10).

Conductivity in the San Joaquin River was much higher than in the Tuolumne and ranged from a low of $211 \mu \mathrm{~S}$ at Gardner Cove to a high of $1406 \mu \mathrm{~S}$ at Laird Park.

Turbidity in the Tuolumne River was less than 10.2 Nephelometric Turbidity Units (NTU) except for readings downstream of Fox Grove on 26 January and 02 March that were likely the result of storm runoff. Turbidity also generally increased with increasing distance below La Grange Dam and generally decreased with higher flows.

Turbidity in the San Joaquin River ranged from 14.5 at Gardner Cove to 81.4 NTU measured at Laird Park.

### 3.1.4 Other Fish Species Caught

The numbers of other fish species caught during the seining study by species, location, and date are in Table 4. Fifteen species other than Chinook salmon were caught in the Tuolumne River and 10 other species in the San Joaquin River. Nine of these species were common to both rivers and 15 species were caught overall. Twenty-nine rainbow trout fry ( $21-51 \mathrm{~mm}$ FL) were caught in the Tuolumne River between 17 February to 11 May at OLGB, R5, and TRR.

2010 Summary of Rainbow Trout caught during the Seining Study

| Date | Location | River Mile | Rainbow Catch | Minimum Fork Length (mm) | Maximum <br> Fork <br> Length <br> (mm) | Average Fork Length (mm) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2/17/10 | OLGB | 50.5 | 10 | 24 | 36 | 27.9 |
| 3/2/10 | OLGB | 50.5 | 2 | 29 | 30 | 29.5 |
| 3/2/10 | TRR | 42.3 | 1 | 22 | 22 | 22.0 |

| 3/16/10 | R5 | 48.0 | 1 | 41 | 41 | 41.0 |
| 3/30/10 | OLGB | 50.5 | 1 | 25 | 25 | 25.0 |
| 3/30/10 | R5 | 48.0 | 2 | 34 | 35 | 34.5 |
| 4/13/10 | R5 | 48.0 | 5 | 29 | 51 | 39.8 |
| 5/11/10 | OLGB | 50.5 | 1 | 37 | 37 | 37.0 |
| 5/11/10 | R5 | 48.0 | 1 | 37 | 37 | 37.0 |

## 4 COMPARATIVE REVIEW

### 4.1 SEINE: 1986-2010

Annual TID/MID Tuolumne River seining surveys began in 1986, with the number, location, and sampling frequency of sites having varied over time (Tables $5 \& 6$ ). The number of salmon captured in the Tuolumne has ranged from 120 (1991) to 14,825 (1987) - the total number of salmon captured was 386 in 2010 which is the seventh lowest for all years. In 2010, the average density of salmon in the river was 2.9 salmon per $1,000 \mathrm{ft}^{2}$ and was most similar to densities found in 1997.

The San Joaquin River has been sampled upstream and downstream of the Tuolumne River confluence in each of the study years. The total number of salmon caught has ranged from 0 to 854 with average density much lower than the Tuolumne (Table 5). No salmon were captured in the San Joaquin River this year and in eight other years.

### 4.1.1 Size and Growth

The comparative review of fork length and density is primarily for the 2005-2010 period in this report. Minimum FL found in 2010 remained low, less than 40 mm FL, through April (Fig. 11). In 2010, the increase in average FL during the January to March period was similar in timing and magnitude to the pattern observed in the 2005-2010 period (Fig. 12). After mid-April the average FL declined and then remained somewhat constant due to low numbers of salmon caught and the outmigration of smolts. Maximum FL in 2010 was about average from January through April (Fig. 13). The estimated 2010 growth rate of .65 mm per day was slightly above average for 1986-2010 (Table 5).

### 4.1.2 Fry and Juvenile Salmon Density

In 2010, the density of salmon fry ( $\leq 50 \mathrm{~mm}$ ) in the Tuolumne River peaked on 17 February at a lower level than 2009 (Fig. 14).

The density of salmon juveniles (>50 mm) in 2010 peaked on 30 March most similar in timing to 2006 (Fig. 15).

Combined fry and juvenile densities for the Tuolumne River are shown for the years 2005-2010 (Fig. 16). The 2010 densities peaked on 02 March at 7.8 salmon per $1,000 \mathrm{ft}^{2}$.

### 4.1.2.1 Tuolumne River Section Density

Upper section density of fry generally peaks from early February to early March and steadily declines through March (Fig. 17). For 2010, the density of fry peaked on 17 February and declined to low levels by mid-March. Upper section density of juveniles typically increases beginning in late February and peaks in early April to late May. In 2010, juvenile salmon density peaked on 13 April.

Middle section density of fry generally peaks from early February to mid-March similar timing to the upper section. In 2010, the density of fry peaked on 02 March. Middle section density of
juveniles often peak from late February to late March. In 2010 juvenile density peaked on 30 March.

Lower section density of fry and juvenile salmon has been relatively low in most years. This section was often sampled only at the Shiloh Road location in prior years. Since 1999, two sites have been sampled. Peak density of fry ranged from early March (2005) to mid-March (2006) during the 2005-2010 period. In 2010, no salmon fry were caught in the lower section. Peak density of juveniles ranged from late March (2006) to late April (2005) with no juvenile captured in 2010.

Section abundance indices of fry and juvenile salmon combined were standardized as a percent of the annual riverwide average abundance index and plotted at section midpoints for recent years (Fig. 18). In 2010 the standardized section abundance indices were in the middle range for the upper and middle sections.

### 4.1.2.2 San Joaquin River Density

Densities of salmon caught in the San Joaquin River at Laird Park and Gardner Cove or nearby sites were reviewed to compare relative abundance of salmon upstream and downstream of the Tuolumne River confluence. The abundance indices were calculated for fry and juvenile salmon combined due to low numbers caught. The average salmon abundance at Laird Park, downstream of the Merced confluence, was extremely low for all years during the 1986-2010 period (Fig. 19). The total number of wild salmon caught at Laird Park during this period was 148. No salmon were caught at Laird Park in 2010. The average abundance at Gardner Cove, downstream of the Tuolumne River confluence, was much higher in 1986 and 1999 and moderately higher in 1995, 1998, 2001 and 2006. A total of 1082 salmon were caught at this location during the 1986-2010 period, 509 of which were caught in 1999. No salmon were caught at Gardner Cove in 2010.

### 4.1.3 Tuolumne River Fry Density Versus Number of Female Spawners

A polynomial equation analysis of peak fry density in the Tuolumne River and the estimated total number of female spawners (TID/MID data), from the preceding fall-run, resulted in an Rsquared of .725 for the 1986-2010 period (Fig. 20, Table 7). A similar result with R-squared of .774 was found using average fry density from 15 January -15 March (Figure 21).

### 4.1.4 Other Fish Species

The number of fish species, other than Chinook salmon, caught during 1992-2010 has ranged from 10 to 16 in the Tuolumne River (Table 8). The counts from each site, by date, for fish species caught in 2010 are in Table 4. Fifteen other species were caught, including 5 native species, in the Tuolumne; 10 fish species, including 2 native, were caught in the San Joaquin River in 2010. The number of species caught in the San Joaquin River was low, similar to the three previous years.

Of native species, rainbow trout, hardhead, and riffle sculpin were caught only in the Tuolumne

River and Sacramento pikeminnow and Sacramento sucker were caught in both rivers. Native species recorded in prior years, but not caught in either river in 2010, were Pacific lamprey, Sacramento blackfish, hitch, Sacramento splittail, tule perch, and prickly sculpin.
The number of species observed in the Tuolumne River during the 1992-2010 period of years has remained fairly constant (Table 8). The number of species observed in the San Joaquin River since 2007 has decreased significantly from earlier years.

In 1987 additional sites on the Tuolumne, San Joaquin, Merced and Stanislaus Rivers were sampled occasionally (1987 annual report).

## INTRODUCTION

## Study Area Description

The Tuolumne River is the largest of three major tributaries (Tuolumne, Merced, and Stanislaus Rivers) to the San Joaquin River, originating in the central Sierra Nevada in Yosemite National Park and flowing west between the Merced River to the south and the Stanislaus River to the north (Figure 1). The San Joaquin River itself flows north and joins the Sacramento River in the Sacramento-San Joaquin Delta within California's Central Valley. The Tuolumne River is dammed at several locations for generation of power, water supply, and flood control - the largest impoundment is Don Pedro Reservoir.

The lower Tuolumne River corridor extends from its confluence with the San Joaquin River to La Grange Dam at river mile (RM) 52.2. The La Grange Dam site has been the upstream limit for anadromous fish migration since at least 1871.

Figure 1. Location map of study area on the Tuolumne River.

## Purpose and History of Study

Rotary screw traps (RST) have been operated since 1995 at various locations in the Tuolumne River during the winter/spring period to meet several objectives, including monitoring the abundance and migration characteristics of juvenile salmonids and other fishes, and evaluating reach-specific survival relative to environmental conditions (Table 1). The Turlock Irrigation District and Modesto Irrigation District ('Districts'), and the City and County of San Francisco funded the entire RST program in 1995-97 and 2003-2010 and at 2-3 upstream sites in 19982000.

Current sampling locations include Grayson River Ranch (Grayson - RM 5.2) near the mouth of the Tuolumne River and a site downstream of the city of Waterford (RM 29.8). Rotary screw trap monitoring has been conducted annually near the mouth since 1995 (Shiloh in 1995-1998 and Grayson in 1999-2010) for the purpose of monitoring the abundance and migration characteristics of juvenile salmonids and other fishes. Since 2006, sampling has also been conducted annually near Waterford, about 25 miles upstream of the Grayson site, to provide comparative information on the size, migration timing, and production of juvenile fall-run Chinook salmon, as well as data on other fishes.

Table 1. Rotary screw trap monitoring in the Lower Tuolumne River, 1995-2010.

[^5]${ }^{3}$ Trap efficiency data not available for parr/smolt lifestage at high flows. A range of trap efficiencies from the 7/11 (RM 38) and Deardorff (RM 35.5) traps was used to obtain a range of passage estimates in 2010.

## METHODS

## Juvenile Outmigrant Monitoring

## Sampling Gear and Trapping Site Locations

Rotary screw traps (E.G. Solutions, Eugene, OR) were installed and operated at the Waterford and Grayson sites. The traps consist of a funnel-shaped core suspended between two pontoons. Traps are positioned in the current so that water enters the 8 ft wide funnel mouth and strikes the internal screw core, causing the funnel to rotate. As the funnel rotates, fish are trapped in pockets of water and forced rearward into a livebox, where they remain until they are processed by technicians.

The single Waterford trap was located at RM 29.8, approximately two miles downstream of the Hickman Bridge. The trap was held in place by a $3 / 8$-inch overhead cable strung between two large trees located on opposite banks. Cables fastened to the front of each pontoon were attached to the overhead cable. Warning signs, flashing safety lights and buoys marked the location of the trap and cables for public safety. Sufficient velocity at the trap during 2010 precluded the need for the "wings" used to increase catch efficiency during 2008 and a portion of 2009.

At Grayson two traps were fastened together, in a side-by-side configuration, with $1 / 2$ inch Ultra High Molecular Weight (UHMW) plastic strips that were bolted to each inner-pontoon at the cross-bars. The traps were positioned and secured in place by two 50 lb plow-style anchors (Delta Fast-Set model, Lewmar, Havant, UK). The anchors were fastened to the outer-pontoons of the traps using $3 / 8$-inch stainless steel leader cables (each outer-pontoon was attached to a separate in-line anchor) and the length of each leader cable was adjusted using a manual winch that was bolted to the outer-pontoon. The downstream force of the water on the traps kept the leader cables taut. Sufficient velocity at the traps during 2010 precluded the need for the "weir" structure used to increase catch efficiency during 2008 and 2009.

## Trap Monitoring

Sampling at Waterford began on January 5, 2010. The trap was operated continuously (24 hours per day, 7 days per week) until June 11, 2010, when sampling was terminated due to consistently low catch.

Sampling at Grayson began on January 6, 2010. The traps were operated continuously (24 hours per day, 7 days per week) until sampling was terminated on June 17, 2010, due to consistently low catch.

Traps at both locations were checked at least every morning throughout the sampling period, with additional trap checks conducted as conditions required. During each trap check the contents of the liveboxes were removed, all fish were identified and counted, and any marked
fish were noted. In addition, random samples of up to 50 salmon and 20 of each non-salmon species during each morning check, and up to 20 salmon and 10 of each non-salmon species during each evening check, were anesthetized, measured (fork lengths in millimeters), and recorded. Salmon were assigned to a lifestage category based on a fork length scale, where <50 $\mathrm{mm}=$ fry, $50-69 \mathrm{~mm}=$ parr, and $\geq 70 \mathrm{~mm}=$ smolt. In addition, the smolting appearance of all measured salmon and trout was rated based on a seven category scale, where $1=$ yolk-sac fry, 2 = fry, $3=$ parr, $4=$ silvery parr, $5=$ smolt, $6=$ mature adult, and IAD $=$ immature adult (Interagency Ecological Program, unpublished). Weights (to nearest tenth of a gram) were taken from up to 50 salmon each week (i.e., Monday through Sunday) and from all trout using a digital balance (Ohaus Corporation, Pine Brook, NJ). Fish were weighed in a small, plastic container partially filled with stream water, which was tared prior to measuring each individual fish. Fish were then placed in a container with freshwater and allowed to recover before release.

Daily salmon catch was equivalent to the number of salmon captured during a morning trap check plus the number of salmon captured during any trap check(s) that occurred within the period after the previous morning check. For example, the daily salmon catch for April 10 is the sum of salmon from the morning trap check on April 10 and the evening trap check conducted on April 9. Separate daily catch data were maintained for marked and unmarked salmon.

After all fish were measured and recorded, the traps were cleaned to prevent accumulation of debris that might impair trap rotation or cause fish mortality within the liveboxes. Trap cleaning included removal of debris from all trap surfaces and from within the liveboxes. The amount of debris load in the livebox was estimated and recorded whenever a trap was checked.

## Trap Efficiency Releases

Trap efficiency tests using naturally produced juvenile salmon were conducted to estimate the proportion of migrating juvenile salmon sampled by the Waterford trap. Juvenile salmon captured in the Waterford trap were used to conduct tests whenever catches were sufficient to obtain a group of at least 30 fish over no more than two days. Eleven groups of naturally produced juvenile salmon (ranging in number from 29 to 116 fish) were marked and released at RM 30 (about 0.2 miles upstream of the trap) between January 21 and March 14. All marked fish were released after dark. Catches of naturally produced juvenile salmon at Waterford after March $14^{\text {th }}$ were insufficient for trap efficiency tests. Likewise, catches of natural fish throughout the study period were insufficient for trap efficiency tests to be conducted at Grayson. Additionally, hatchery produced fish were not available for tests during 2010. Trap efficiency calculations for both sites are discussed in further detail below.

## Holding Facility and Transport Method

Juvenile salmon were transferred from liveboxes into either 5-gallon buckets or 20-gallon insulated coolers depending on the number of fish, temperature, and distance traveled, and were
transported by boat upstream to the release site.
At release sites, fish were held in livecars constructed of 15 " diameter PVC pipe cut into 34 " lengths (Figure 2). A rectangle approximately 6 " wide by 23 " long was cut longitudinally along the pipe and fitted with aluminum or stainless steel mesh. Livecars were tethered to vegetation or other structures and kept in areas of low water velocity to reduce fish stress.

Figure 2. Livecar used for holding trap efficiency test fish.

## Marking Procedure

At the Waterford trapping site, naturally produced juvenile salmon were marked onshore immediately adjacent to the trap and were then transported to the release site where they were held until release. A photonic marking system was used for marking all of the release groups because of the high quality of marks and the ability to use the marking equipment in rapid succession. All fish were anesthetized with Tricaine-S before the appropriate mark was applied, and then a marker tip was placed against the caudal fin and orange photonic dye was injected into the fin rays. The photonic dye (DayGlo Color Corporation, Cleveland, OH) was chosen because of its known ability to provide a highly visible, long-lasting mark.

## Pre-release Sampling

Prior to release, marked fish were sampled for length and mark retention. Fifty fish (or the entire release group if fewer than 50 fish) were randomly selected from each release group, anesthetized, and examined for marks; the remaining fish in each group were enumerated. Mark retention was rated as present or absent. A total of zero fish in 2010 were found to have no marks upon examination, consequently, all fish released were presumed to have visible marks.

## Release Procedure

Livecars were located several feet away from the specific release point and fish were poured from the live cars into buckets for release. Fish were released by placing a dip net into the bucket, scooping up a "net-full" of fish and then emptying the fish into the river, allowing them to swim away. After releasing a "net-full" of fish, about 30 seconds to 3 minutes elapsed before another group of about a "net-full" was released. The amount of time between "net-full" releases varied depending on how fast fish swam away after their release. Total release time for marked groups ranged from ten minutes to 30 minutes depending on the group size.

## Monitoring Environmental Factors

## Flow Measurements and Trap Speed

Provisional daily average flow for the Tuolumne River at La Grange was obtained from USGS at http://waterdata.usgs.gov/ca/nwis/dv/?site no=11265000\&agency cd=USGS. Provisional daily average flow for the Tuolumne River at Modesto was obtained from the USGS at http://waterdata.usgs.gov/ca/nwis/dv/?site_no=11290000\&agency_cd=USGS. The Modesto flow station is below Dry Creek, the largest seasonal tributary entering the river downstream of La Grange Dam. As a result, that site includes flow associated with major winter runoff events. Velocity of water entering the traps was measured using two methods. First, the water velocity entering the traps was measured daily with a Global Flow Probe (Global Water, Fair Oaks, CA). Second, an average daily trap rotation speed was calculated for each trap, by recording the time (in seconds) for three continuous revolutions of the cone, once before and once after the morning trap cleaning. The average of the two times was considered the average daily trap rotation speed.

## River Temperature, Relative Turbidity and Dissolved Oxygen

Instantaneous water temperature was measured daily with a mercury thermometer at the trap site. Data were also available from hourly recording thermographs maintained by the Districts at both trapping sites. To measure daily instantaneous turbidity, a water sample was collected each morning and later tested at the field station with a LaMotte turbidity meter (Model 2020e, LaMotte Company, Chestertown, MD). Turbidity was recorded in nephelometric turbidity units (NTU). Instantaneous dissolved oxygen was measured during trap checks with an ExStik ${ }^{\circledR}$ II D600 Dissolved Oxygen Meter (Extech Instruments Corporation, Waltham, MA) at the trapping sites and recorded in milligrams per liter ( $\mathrm{mg} / \mathrm{L}$ ).

## Estimating Trap Efficiency and Chinook Salmon Abundance

The estimated daily number of fish passing each site was generated by either expanding the catch data by the average estimated trap efficiency for the lifestage captured (Waterford) or by a trap efficiency predictor equation (Grayson).

There is a limited trap efficiency dataset for Waterford because sampling has only been conducted since 2006, and the data are currently inadequate for developing regression relationships between trap efficiency and explanatory variables such as river flow, fish size, or turbidity. In the future, when more tests have been conducted, a multiple regression may be developed similar to the one described below for the Grayson trap. In the interim, an estimate of salmon relative abundance for the sampling season was calculated by expanding the daily number of fish by the average observed trap efficiency for each lifestage using the best available data. Trap efficiency releases were only conducted for the fry lifestage in 2010 due to insufficient catch during the parr/smolt outmigration period. In some situations hatchery origin fish have also been used for trap efficiency tests, however, fish from the Merced River Hatchery were not available during 2010.

Salmon fry abundance estimates were generated based on trap efficiency tests conducted in 2010 at Waterford. Since no efficiency estimates were available for parr/smolt in 2010, the abundance of parr/smolt at Waterford was calculated as follows:

1. Abundance estimates during flows less than $1,000 \mathrm{cfs}$ were calculated using all results from tests conducted during 2007 with parr/smolt at Waterford under similar flows.
2. Abundance estimates during flows greater than $1,000 \mathrm{cfs}$ were calculated using all results from tests conducted at the $7 / 11$ (RM 38) and Deardorff (RM 35.5) sites under similar flow conditions during 1998-2000 using fish approximately $60-95 \mathrm{~mm}$ (Stillwater Sciences 2001). Since these estimates were taken from different (but comparable) locations, a range of parr/smolt abundances were calculated to account for the uncertainty in trap efficiencies at Waterford during higher flows (i.e., greater than 1,000cfs).

At Grayson, daily trap efficiencies were estimated based on a multiple regression equation developed using flow and trap efficiency data collected from 1999 through 2008. Specifically, average daily river flow at Modesto, average fish size at release, and natural log transformed proportions of fish recovered from each release event were used to develop the following trap efficiency predictor equation (adjusted $\mathrm{R}^{2}=0.64$ ):

Daily Predicted Trap Efficiency $=\operatorname{EXP}(-0.29176+(-0.00042 *$ Flow at MOD $)+(-0.03410 *$ Fish size $))$
where Flow at MOD= daily average river flow (cfs) at Modesto Fish size $=$ daily average fork length $(\mathrm{mm})$ of fish captured at Grayson

These daily predicted trap efficiencies (DPTE) were then applied to the daily catch (DC) to estimate daily passage as follows:

Estimated Daily Passage= DC/DPTE

## RESULTS AND DISCUSSION

## Chinook Salmon

## Number of Unmarked Chinook Salmon Captured

Juvenile salmon sampled in the 2010 RST operation were the progeny of an estimated 282 salmon ( 87 females) that spawned in the fall of 2009 (Cuthbert et al. 2010). The fall-run juvenile salmon outmigration in the San Joaquin Basin typically occurs during the winter and spring, extending mainly from January through May. The outmigration consists largely of fry in winter that are typically less than 50 mm fork length, and smolts in spring which are typically greater than 69 mm fork length. There are also some larger fish that migrate mostly in winter and some fry observed in late spring, which may be from salmon with different spawn timing than fall-run.

During 2010, catches of juvenile Chinook salmon at Waterford were highest in early to midMarch and primarily consisted of fry ( $<50 \mathrm{~mm}$; Figure 5). Daily salmon catch peaked on January 22 (mainly fry $<50 \mathrm{~mm}$ ) following several days of rain, which began on January 18. Daily catches of juvenile salmon at Waterford between January 5 and June 11 ranged from zero to 128 fish, with a total catch of 2,281 salmon (Figure 3).

At Grayson, catches of juvenile salmon in 2010 were highest in late January and May during the fry and smolt outmigration periods, respectively. Daily catches of juvenile salmon at Grayson between January 6 and June 17 ranged from zero to six fish, with a total catch of 52 salmon (Figure 4). The total numbers captured by lifestage at each site are presented in Table 2.
Table 2. Catch by lifestage at Waterford and Grayson, 2010.

|  | Fry $(<50 \mathrm{~mm})$ | Parr $(50-69 \mathrm{~mm})$ | Smolt $(\geq 70 \mathrm{~mm})$ |
| :--- | :---: | :---: | :---: |
| Waterford | 1,241 | 69 | 971 |
| Grayson | 13 | 0 | 39 |

Sampling at Waterford was considered comprehensive and covered January through May each year the trap was sampled. However, in 2006 the sampling was initiated a few weeks later than usual and there was an extended non-sampling period (April 12-21) due to high flows; therefore, outmigration was not fully sampled during the 2006 season. In 2010, the total annual catch of juvenile salmon at Waterford was approximately one-third less than the three previous years (i.e., 2007-2009) and only $25 \%$ of the number of Chinook captured in 2006, despite the abbreviated sampling during that year (Table 1; Figure 5). Total annual trap catch at Waterford from 20062010 ranged from a high of 9,106 in 2006 to a low of 2,281 in 2010, and averaged 4,346 juvenile salmon (Figure 5). The variation in catch during 2006 is likely due to environmental conditions,
specifically high flows that averaged approximately 5,300 cfs during the juvenile migration season (i.e., January-May/June) and higher overall abundance. The lower catch in 2010 is likely due to environmental conditions during the smolt outmigration period when flows averaged approximately $2,400 \mathrm{cfs}$ and lower overall abundance. Trap efficiency decreases at higher flows, specifically when flows are higher than approximately $1,000 \mathrm{cfs}$.

Total annual catch of juvenile salmon has varied substantially between years at Grayson/Shiloh (Table 1; Figure 6). This variation is likely due to differences in one or more factors including, the duration and timing of the sampling periods, environmental conditions, and overall fish abundance and survival (Table 1). Sampling periods have varied between years, with sampling initiated as early as January or as late as April and continuing through May/June.

During 1999-2002, 2006, and 2008-2010, sampling at Grayson encompassed the majority of the expected winter/spring outmigration season (i.e., January-May/June) and can be described as comprehensive (Table 1; Figure 6). In contrast, sampling was only conducted during the spring smolt outmigration period (i.e., April-May/June) in 1995-1997 at Shiloh and 2003-2005 and 2007 at Grayson, therefore sampling was incomplete for those years. Sampling during 1998 began in February but was limited to a single trap (Note: two traps were operated in all other years); thus, 1998 sampling covered an intermediate proportion of the entire outmigration period. The proportion of the Jan-May outmigration period monitored each year ranged from $82 \%$ to $98 \%$ during winter/spring sampling years, from $24 \%$ to $44 \%$ during spring-only sampling years, and was $70 \%$ in the intermediate sampling year (Table 1). The proportion of the outmigration period sampled may not be representative of the proportion of the juvenile population migrating during the sample period because the migration pattern is not uniform. Migration timing can be influenced by environmental factors such as flow and turbidity, which are often highly variable during the outmigration period.

Of the winter/spring sampling years, total annual trap catch at Grayson ranged from a high of 19,327 during 1999 to a low of 52 during 2010, and averaged 3,806 juvenile salmon (Figure 6). In all years of spring-only sampling, catches ranged from a high of 1,239 during 2001 to a low of 27 during 2007.

Figure 3. Daily catch of unmarked Chinook salmon at Waterford and river flow at La Grange (LGN) during 2010.

Figure 4. Daily catch of unmarked Chinook salmon at Grayson and river flow at Modesto (MOD) during 2010. Note: Flow at MOD is estimated on Jan. 8-Jan. 15; Jan. 21-Jan. 24; Feb. 11-Mar. 23; Apr. 21-Jun. 14; Jun. 16-Jun. 19; and Jun. 26-30 due to a malfunctioning gage.

Figure 5. Total annual salmon catch at Waterford during 2006-2010.

Figure 6. Total annual salmon catch at Shiloh/Grayson during 1995-2010.

## Trap Efficiency

In 2010, eleven trap efficiency tests were conducted at Waterford using naturally produced salmon fry. Results from these tests ranged from $2.9 \%$ to $20.0 \%$ at flows (La Grange) between 223 cfs and 227 cfs (Table 3; Figure 7). No trap efficiency estimates were obtained during the parr/smolt outmigration period due to insufficient catch in the Waterford trap and the lack of hatchery fish available for releases. Average fork length at release for the trap efficiency test groups in 2010 ranged from 35 mm to 37 mm ( $\mathrm{n}=11$, Table 3). As mentioned previously, since flows were higher in 2010 than in recent years and there were no comparable trap efficiency data available for the Waterford trap at flows greater than $1,000 \mathrm{cfs}$, data were used from past test results conducted under similar flow conditions at the $7 / 11$ (RM 38) and Deardorff (RM 35.5) traps (Table 3; Stillwater Sciences 2001). Consequently, in order to account for the uncertainty in trap efficiencies at higher flows at Waterford, a range of parr/smolt abundances were calculated from data collected in previous years during periods flows greater than 1,000 cfs.

Thus, salmon abundance estimate calculations at Waterford in 2010 were based on (Table 3):
Fry:

- trap efficiency tests conducted in 2010 at Waterford $=11.1 \%$

Parr/Smolt:

- trap efficiency tests conducted in 2007 at Waterford at flows < 1,000cfs $=5.3 \%$
- trap efficiency tests conducted in 1998-2000 at the 7/11 trap (RM 38; 1998 and 1999) and the Deardorff trap (RM 35.5; 2000) at flows > 1,000cfs $=2.0-5.6 \%$

At Grayson, observed trap efficiency estimates from 1999-2008 ranged from zero to $21.2 \%$ at flows (Modesto) ranging between 280 cfs and $7,942 \mathrm{cfs}$ (Table 4; Figure 8). No trap efficiency estimates were obtained at Grayson during 2010 due to insufficient catch in the traps and the lack of hatchery fish available for releases.

Daily predicted trap efficiency, and daily estimated passage at Waterford and Grayson in 2010 are provided in Appendices A and B, respectively.

Table 3. Trap efficiency results used to estimate daily trap efficiencies at Waterford. Note: Only releases for the fry lifestage were conducted in 2010 . Results from 2007 were used for predicting daily trap efficiencies during the parr/smolt lifestages at flows less than 1,000 cfs. Historical trap efficiency data from the 7/11 (RM 38) and Deardorff (RM 35.5) traps were used during the parr/smolt lifestages at flows greater than 1,000 cfs.

Figure 7. Trap efficiency estimates at Waterford relative to river flow at La Grange (LGN) during 2010.

Figure 8. Trap efficiency observations at Grayson relative to river flow at Modesto (MOD), 1999-2008.

## Estimated Chinook Salmon Abundance

As mentioned previously, in order to account for the uncertainty in trap efficiencies at Waterford during periods of parr/smolt outmigration (April 11-June 10), a range of abundances were calculated using trap efficiency data from previous study years. In this section, for ease of explanation, the population estimate was calculated using the median historical efficiency with the range in parentheses (Figure 9). Based on calculated daily passage estimates, an estimated 42,600 (29,300-55,900) Chinook salmon passed Waterford during 2010, of which $70.7 \%$ ( $58.2 \%-77.2 \%$ ) were smolts (Table 5). In comparison, the percentage of fish passing Waterford as smolts was $51.7 \%$ in 2009, $34.3 \%$ in 2008, and $51.1 \%$ in 2007. In 2006, sampling efforts were affected by high spring flows resulting in passage estimates that were likely underestimated (particularly for smolts). Similar to the pattern observed for catch in 2010, and in previous years, it is estimated that a majority of the salmon passing Waterford in 2010 prior to mid-March were fry and passage was then dominated by smolts from late-March through May (Table 5; Figure 10). Daily estimated salmon passage at Waterford ranged from zero to 1,730 (max. range $=$ $1,153-2,550$ ). The peak in daily passage for fry occurred on January 21 and smolt passage peaked on May 15 (Figure 11).

During the 2009-2010 spawning season, approximately 490 (337-643) juveniles were produced per female spawner relative to the estimated $87^{3}$ female spawners; compared to 175 juveniles in 2009, 311 in 2008, and 205 in 2007 (Table 6). Beginning in 2010 the number of female spawners was estimated using counts from a Vaki Riverwatcher used in conjunction with a resistance board weir, rather than using the traditional carcass surveys. This estimate of spawner abundance is believed to be more accurate than carcass surveys, especially during years of lower abundance (Cuthbert et al. 2010).

Figure 9. Daily estimated abundance of Chinook salmon at Waterford based on trap efficiencies conducted in 2010 at Waterford during the fry period, and trap efficiencies conducted in 2007 at Waterford (at flows < $1,000 \mathrm{cfs}$ ) and at the $7 / 11$ and Deardorff traps in 1998-2000 (at flows $>1,000 \mathrm{cfs}$ ) for the parr/smolt period. A range of abundances were calculated for the parr/smolt period and the median and range are presented in this graph.

[^6]Table 5. Estimated passage by lifestage at Waterford and Grayson during 1995-2010. *For 2010 the estimated passage values used in this table for Waterford are the median values of the estimated ranges.

Table 6. Estimated number of juvenile salmon produced per female spawner, 2006-2010.

|  | Females | Juveniles/female spawner |
| :---: | :---: | :---: |
| $\mathbf{2 0 0 6}$ | 478 | 635 |
| $\mathbf{2 0 0 7}$ | 282 | 205 |
| $\mathbf{2 0 0 8}$ | 80 | 311 |
| $\mathbf{2 0 0 9}$ | 212 | 175 |
| $\mathbf{2 0 1 0}$ | 87 | 337 to 643 |

An estimated 4,443 unmarked Chinook salmon passed Grayson during 2010 and $95.9 \%$ of these were smolts (Table 5). Daily estimated passage at Grayson ranged from 0 to 718 salmon. Peak daily passage for smolts occurred on May 20 (Figure 12). During comparable seasonal sampling in previous years at Grayson (i.e., winter/spring sampling in 1999-2002, 2006, and 2008-2009), total estimated passage ranged from a high of 755,604 in 1999 to a low of 3,283 in 2008 (Table 1; Figure 14); the proportion of passage as smolts was the highest in $2010(95.9 \%)$ and the lowest in 1999 (4.0\%). In spring-only sampling years at Grayson/Shiloh (i.e., 2003-2005 and 2007 at Grayson and 1995-1997 at Shiloh), total estimated passage ranged from a high of

255,710 in 2005 to a low of 937 in 2007 (Table 1; Figure 14); the vast majority of migrants in all spring-only years were smolts (>95.0\%; Table 5). Among all years, estimated passage was the highest during 1998 (Table 1; Figure 14), when sampling effort was intermediate and the proportion passing as smolts was low ( $5.7 \%$ ). However, the 1998 passage estimate of 1,615,673 fish may be inflated and the proportion passing as smolts may be underestimated because no trap efficiency tests were conducted with fry.

NOTE: From April 11-June 10 the graph depicts median daily passage estimates - See Figure 9.

Figure 12. Daily estimated passage of unmarked Chinook salmon at Grayson and river flow at Modesto (MOD) during 2010.

Figure 13. Total estimated Chinook passage at Waterford (2006-2010).
*Note that 2010 estimates are based upon the median of historical trap efficiency. ( ${ }^{*}$ range $=29,300-55,900$ ).

Figure 14. Total estimated Chinook passage at Shiloh and Grayson during 1995-2010.

## Estimated Chinook Salmon Abundance and Environmental Factors

Peaks in salmon fry passage at Waterford in the winter were generally associated with peaks in turbidity conditions. River releases were relatively stable during this period (January-midMarch) and ranged from 222 cfs to 259 cfs. River flow near Grayson during the winter period was more variable as a result of storm run-off, particularly from Dry Creek entering at Modesto, and ranged from 279 cfs to $1,423 \mathrm{cfs}$. During the spring (mid-March through June), higher pulse flows produced several peaks in flow at both traps (Figure 11 and Figure 12).

During 2010 monitoring, daily average water temperatures ranged from $49.6^{\circ} \mathrm{F}$ to $60.4^{\circ} \mathrm{F}$ at the Waterford trap (Figure 15) and from $47.7^{\circ} \mathrm{F}$ to $64.2^{\circ} \mathrm{F}$ at the Grayson traps (Figure 16). Water temperatures generally increased through the outmigration season, with two peaks in mid- and late-March. There were no obvious correlations between trends in passage and water temperature during 2010.

Figure 15. Daily estimated passage of unmarked Chinook salmon and daily average water temperature at the Waterford trap during 2010. NOTE: From April 11-June 10 the graph depicts median daily passage estimates - See Figure 9.

Figure 16. Daily estimated passage of unmarked Chinook salmon and daily average water temperature at the Grayson trap during 2010.

Background turbidity was generally less than 4 NTU at Waterford (Figure 17) and less than 6 NTU at Grayson (Figure 18) during the 2010 monitoring period. During several storm events (Figure 19), spikes in turbidity were observed ranging as high as 33 NTU at Waterford, and ranging as high as 81 NTU at Grayson. Peaks in passage on January $21^{\text {st }}$ and February $9^{\text {th }}$ at Waterford coincided with periods of elevated turbidity.

The ratio of estimated total passage at Grayson relative to the estimated total passage at Waterford provides an index of survival through the river between the sites ( 24.6 miles) during years when the majority of the outmigration period is sampled. The survival index for 2010, $10.4 \%$, should be interpreted with caution, since there is substantial uncertainty in the total passage estimate for Waterford. This value was calculated using the median estimated total passage for Waterford, and ranges from $7.9 \%$ to $15.2 \%$ based upon the range of estimated passages. Survival indices of $23.6 \%, 13.2 \%$ and $11.9 \%$ were calculated for 2006, 2008 and 2009, respectively. A survival index was not calculated for 2007 because sampling did not begin until mid-March.

Figure 17. Daily estimated passage of unmarked Chinook salmon and instantaneous turbidity at Waterford during 2010. NOTE: From April 11-June 10 the graph depicts median daily passage estimates - See Figure 9.

Figure 19. Daily rainfall measured at Don Pedro Reservoir and instantaneous turbidity at Waterford during 2010.

Chinook Salmon Length at Migration

Individual fork lengths of unmarked salmon captured at Waterford during 2010 ranged from 30 mm to 140 mm (Figure 20), and daily average length gradually increased from approximately 36 mm to over 90 mm during the course of the sampling period (Figure 21 and Figure 22). Most of the juvenile salmon passing Waterford during 2010 were smolts measuring $80-109 \mathrm{~mm}$, followed by fry measuring $30-39 \mathrm{~mm}$ (Figure 23). In total, it is estimated that 11,471 fry ( $<50 \mathrm{~mm}$ ), 1,023 parr ( $50-69 \mathrm{~mm}$ ), and 30,124 smolts ( $\geq 70 \mathrm{~mm}$ ) passed Waterford during 2010 (Table 5). There were also a number of fish captured throughout the season that were atypical sizes for fall-run Chinook salmon production (Figure 20). For instance, during January through mid-March there were 47 fish much larger than the majority of juvenile salmon captured during that period (average size of larger fish was over 60 mm larger than majority of juvenile salmon captured) and 10 fish in the spring that were much smaller than other juvenile salmon captured during that period ( $34-38 \mathrm{~mm}$ versus $45-125 \mathrm{~mm}$ ).

Individual fork lengths of unmarked Chinook salmon captured at Grayson during 2010 ranged from 31 mm to 139 mm (Figure 24), and daily average length ranged between 31 mm and 110 mm during the sampling period (Figure 25 and Figure 26). Nearly $78 \%$ of the salmon estimated to have passed Grayson during 2010 were smolts measuring $90-109 \mathrm{~mm}$ (Figure 26). In total, it is estimated that 183 fry ( $<50 \mathrm{~mm}$ ), zero parr ( $50-69 \mathrm{~mm}$ ), and 4,260 smolts ( $\geq 70 \mathrm{~mm}$ ) passed Grayson during 2010 (Table 5). Similar to Waterford, three much larger sized Chinook were also captured during January through early March (Figure 24).

Figure 26. Estimated Chinook passage by 10 mm fork length intervals at Grayson during 2010.

## Chinook Salmon Condition at Migration

Juveniles captured at both Waterford and Grayson during 2010 were generally healthy with no apparent signs of disease or stress. The relationship between individual salmon fork length and weight showed a very similar trend between Waterford and Grayson (Figure 27).

Figure 27. Fork length and weight of individual juvenile Chinook salmon measured at Waterford and Grayson during 2010.

## Oncorhynchus mykiss (Rainbow Trout/Steelhead)

No $O$. mykiss were captured at Waterford or Grayson in 2010. Total annual O. mykiss catch at the Grayson and Waterford traps between 2007 and 2010 ranged from zero to eleven (Figure 28).

Figure 28. Date, size and location of $\boldsymbol{O}$. mykiss captured at Waterford (W) and Grayson (G).

## Other Fish Species Captured

A total of 4,467 non-salmonids representing at least 22 species ( 5 native, 17 introduced) were captured during operation of the Waterford and Grayson traps in 2010 (Table 7; Appendices C and D). Native species comprised $56.7 \%$ of the total non-salmonid catch, consisting primarily of lamprey ( $\mathrm{n}=1,952$ ). Most species captured at Waterford were also recorded at Grayson. Additional species only recorded at Waterford were green sunfish and tule perch. Species only recorded at Grayson were bigscale logperch, black bullhead, brown bullhead, black crappie, goldfish, and inland silverside. Lampreys captured in the traps were primarily ammocoetes and were not identified to species or measured. No adult lamprey were captured at either trapping location.

Table 7. Non-salmonid species captured at Waterford and Grayson during 2010. Native species are indicated in bold.

# 2010 LOWER TUOLUMNE RIVER ANNUAL REPORT 

Report 2010-5<br>2010 Snorkel Report and Summary Update

Prepared for
Turlock and Modesto Irrigation Districts

By
Steve Kirihara
Stillwater Sciences
Berkeley, CA

## SUMMARY

In 2010, higher summer flows in June and July precluded conducting the early summer reference count snorkel survey within the 20-mile reach of the Tuolumne River below La Grange Dam. The 3-day survey was instead conducted on 10-12 August, with an additional survey conducted on 02-04 November. Preliminary USGS flow at La Grange was about 315 cfs and water temperature ranged from $11.1^{\circ} \mathrm{C}(52.0 \mathrm{~F})$ to $20.1^{\circ} \mathrm{C}(68.2 \mathrm{~F})$ in August and flow was about 360 cfs with water temperatures from $11.7^{\circ} \mathrm{C}(53.1 \mathrm{~F})$ to $14.3^{\circ} \mathrm{C}(57.7 \mathrm{~F})$ in November. A total of 152 juvenile Chinook salmon (Oncorhynchus tshawytscha) and 268 rainbow trout (Oncorhynchus mykiss) were observed in various habitats in August and 170 Chinook salmon (including adult spawners) and 218 rainbow trout were observed in November. Chinook salmon were observed downstream to Riffle 57 (River Mile [RM] 31.5) and rainbow trout downstream to Riffle 31 (RM 38.0) in August and Chinook salmon and rainbow trout were both observed downstream to Riffle 41A (RM 35.3) in November. Other native fish species observed were Sacramento sucker, Sacramento pikeminnow, hardhead, Pacific lamprey, and riffle sculpin with the non-native species recorded being largemouth bass, smallmouth bass, redear sunfish, and striped bass during the two surveys.

Early summer surveys in June/July have been conducted in most years since 1986 except in years with high flows (1995, 1998, 2005, 2006, and 2010) that precluded the surveys.

Late summer surveys have been conducted in September of most years during the 2001-2010 period with the exception of 2008 and 2009. Rainbow trout were observed in all years surveyed with the highest counts seen in 2006 and the second highest counts seen in 2010 (August and November). Chinook salmon were seen in much lower numbers or not at during the late summer surveys over the same period of years with the highest counts observed in 2010.

Summer distribution of non-salmonid species (species other than trout or salmon) shifted beginning in 1996. Prior to then, warmwater species (e.g. common carp, goldfish, catfish species, and sunfish species) were commonly observed, even upstream to Riffle 2 (RM 49.9). After 1996, these species were observed less frequently and typically only further downstream. The change in species distribution coincided with higher required summer flows and associated cooler water temperatures occurring in non-flood release years.

## 1 INTRODUCTION

The Turlock and Modesto irrigation districts (Districts) Tuolumne River snorkel surveys began in 1982 and the number, location, area sampled by site and season having varied over the years. The surveys completed from 1982-1987 were in limited locations and in varying seasons. A June/July snorkel survey has often been conducted since 1986 to evaluate the abundance, size, and distribution of salmonids and other fish species in "early summer" when required flow releases are less than in other seasons and subsequent to the primary outmigration period of juvenile salmon. "Summer" surveys during June through September have been conducted in most years since 1988, although very wet years with high summer flows were not sampled for safety reasons. The surveys in 1988-1994 were part of the Districts' "summer flow" studies examining conditions affecting Chinook salmon (O. tshawytscha) while those since 1996 were part of the Tuolumne River fish management program implemented under the current FERC license for the Don Pedro Project. A total of 12 sites per survey have been included since 2001 and a comparable September snorkel survey was included in 2001-2007 and again in 2010. In 2010 the survey was conducted in August and was repeated in November. The 2010 surveys were implemented as required studies under the FERC order issued 10 May 2010 regarding Oncorhynchus mykiss.

Locations were selected to include a range of habitat types (i.e., riffles, runs, pools) at sites where salmonids may occur and are spaced at intervals down the river in general areas of suitable access. The overall river section examined is limited to the reach with suitable underwater visibility, this generally being about a 20-mile section from La Grange Dam (RM 52.2) downstream to near the city of Waterford (RM 31.5), although one site near RM 25 was sampled in 1988-1993.

### 1.1 2010 STUDY SITES

The area studied was the Tuolumne River from La Grange Dam (RM 52.2) to Hickman Bridge (RM 31.5) (Figure 1). Sites were selected based upon historical observations of fish habitat use, with presence/absence of fish at these sites and relative numbers used as indicators of river conditions such as flow and temperature. A total of twelve sites sampled are listed below. Riffle names are interchangeably designated with a "R" in this report (i.e. R21 = Riffle 21).

| Site | Location | River Mile $^{\text {a }}$ |
| :--- | :--- | :--- |
| 1 | Old La Grange Bridge (Riffle A7) | 50.7 |
| 2 | Riffle 2 | 49.9 |
| 3 | Riffle 3B | 49.1 |
| 4 | Basso Bridge (R5B) | 47.9 |
| 5 | Riffle 7 | 46.9 |
| 6 | Zanker Farm (R13B) | 45.5 |
| 7 | Bobcat Flat (R21) | 42.9 |
| 8 | Tuolumne River Resort (R23C) | 42.3 |
| 9 | 7/11 Gravel (R31) | 38.0 |
| 10 | Santa Fe Gravel (R35A) | 37.1 |
| 11 | Deardorff Farm (R41A) | 35.3 |
| 12 | Hickman Bridge (R57) | 31.5 |

${ }^{\text {a }}$ derived from topographic maps as distance from confluence with the San Joaquin River

### 1.2 2010 SAMPLING CONDITIONS

The flow at La Grange during 10-12 August was approximately 315 cfs and approximately 360 cfs during the 02-04 November survey (Figure. 2). Water temperature ranged from $11.1^{\circ} \mathrm{C}$ (52.0 ${ }^{\circ} \mathrm{F}$ ) at Riffle A7 on 10 August to $20.1^{\circ} \mathrm{C}\left(68.2^{\circ} \mathrm{F}\right)$ at Riffle 57 on 12 August and $11.7^{\circ} \mathrm{C}$ ( $53.1^{\circ} \mathrm{F}$ ) on 02 November to $14.3^{\circ} \mathrm{C}\left(57.7^{\circ} \mathrm{F}\right.$ ) on 04 November at these same locations. The higher flows sampled this year required some modification to the survey methods as noted in the methods section.

## 2 METHODS

Underwater observations were conducted using an effort-based method where a snorkeler examined within a specified area for a given period of time and recorded the species, numbers, and size estimates of fish observed. A combination of different habitat types was observed, including riffles, runs, and pools. The overall river section examined is limited to the reach with suitable underwater visibility, this generally being a 20 -mile section below La Grange Dam downstream to near the city of Waterford. The snorkeling method provided an index of species abundance and these surveys are currently referred to as "reference counts".

Each habitat type sampled usually involved one observer who snorkeled the specified habitat area for a certain time period. Whenever feasible, the surveys were conducted moving upstream against the current. A side-to-side (zigzag) pattern was used as the width of the survey section required. Occasionally, two snorkelers moved upstream in tandem, with each person counting fish on their side of the center of the survey section. Whenever possible, the entire width of the habitat section selected was carefully surveyed. The only exceptions were the habitat areas that were too wide to effectively cover. If high water velocity precluded upstream movement, snorkelers would float downstream with the current, remaining as motionless as possible through the study area, although stream margins at those sites would still be viewed in an upstream direction. The 2010 surveys required more areas to be searched utilizing the downstream float method.

Usually the total length of an observed fish was estimated using scale markings on the diving slate and recorded to the nearest 10 mm . For some larger fish, the lengths may be estimated by viewing the fish in reference to adjacent objects and then measuring that estimated length. In cases where larger numbers of fish are observed, the observer estimated the length range and number of fish in the group. Care was taken to observe and count each fish just once in the survey area.

Other data recorded for each location included water temperature, electrical conductivity, turbidity, dissolved oxygen, and horizontal visibility. Site-specific data that was recorded included area sampled, average depth, sample time, general habitat type, and substrate type.

## 3 RESULTS AND DISCUSSION

Survey conditions and fish observations from the snorkel survey conducted on 10-12 August and $02-04$ November are summarized in Tables 1 and 2, respectively. The seven native fish species observed were characteristic of the lower elevation zone adjacent to the Sierra foothills. These
species were Chinook salmon, rainbow trout, Sacramento sucker (Catostomus occidentalis), Sacramento pikeminnow (Ptychocheilus grandis), hardhead (Mylopharodon conocephalus), Pacific lamprey (Lampetra tridentata) and riffle sculpin (Cottus gulosus). The introduced (nonnative) species observed were largemouth bass (Micropterus salmoides), smallmouth bass (Micropterus dolomieu), redear sunfish (Lepomis microlophus), and striped bass (Morone saxatilis).

Chinook salmon were observed downstream to R57 (RM 31.5) and rainbow trout to R31 (RM 38.0) in August and both species were observed downstream to R41A (RM 35.3) in November.

During the August surveys, there were 152 juvenile Chinook salmon observed in riffle, run, and run-pool habitats from RA7 (RM 50.7) near La Grange Dam downstream to R57 (RM 31.5), ranging in size from 50-170 mm total length (TL). There were 268 rainbow trout observed ranging in size from 40-480 mm TL and were seen in riffle, run, and run-pool habitats. A total of 195 juvenile ( $<150 \mathrm{~mm} \mathrm{TL}$ ) and 73 adult rainbow trout were observed between RA7 (RM 50.7) and R31 (RM 38.0). Fish were observed in riffle, run, and run-pool habitats. Water temperature at those locations ranged from $11.1^{\circ} \mathrm{C}(52.0 \mathrm{~F})$ to $16.3^{\circ} \mathrm{C}(61.3 \mathrm{~F})$. Sacramento sucker along with Sacramento pikeminnow and hardhead were often co-occurring, while riffle sculpin were observed at 3 locations in low numbers usually hidden under cobble/boulder substrate. Striped bass were observed at R21 (RM 42.9) for the first time during the reference snorkel surveys.

During the November surveys, there were 170 Chinook salmon including 13 adult spawners observed in riffle, run and pool habitats from RA7 (RM 50.7) to R41A (RM 35.3). The juveniles ranged in size from $70-120 \mathrm{~mm}$ TL and the adults ranged in size from 650-920 mm TL . There were a total 218 rainbow trout observed ranging in size from 70-400 mm FL also observed in similar combinations of riffle, run and pool habitats, with 155 juvenile ( $<150 \mathrm{~mm} \mathrm{TL}$ ) and 63 adults observed between RA7 (RM 50.7) and R 41A (RM 35.3). Water temperature ranged from $11.7^{\circ} \mathrm{C}\left(53.1^{\circ} \mathrm{F}\right)$ to $14.2^{\circ} \mathrm{C}\left(57.6^{\circ} \mathrm{F}\right)$ at those locations. Similar to the August survey, Sacramento sucker along with Sacramento pikeminnow and hardhead were often co-occurring, while riffle sculpin were observed at 4 locations in low numbers usually hidden under cobble/boulder substrate. Striped bass were again observed at R21 (RM 42.9).

## 4 COMPARISON WITH OTHER YEARS

### 4.1 Rainbow trout and Chinook salmon: 1982-2010

Tables 3 and 4 summarize rainbow trout and Chinook salmon observations for all snorkel surveys conducted between 1982 and 2010. Some rainbow trout were observed downstream to R5 (RM 48.0) in limited surveys from 1982 to 1986. Rainbow trout were almost entirely absent during 1987 to 1995 surveys. Beginning with the increased summer base flows implemented under the 1996 FERC Order, the number and distribution of rainbow trout increased and since 1999 these fish have been regularly observed at locations downstream to RM 42.9 or RM 42.3. For the 1982-2010 period, Chinook salmon were recorded in all years except 1991 and 1992 although in some years their counts were very low after May. Chinook salmon were also commonly seen downstream to about RM 42.9. Figures 3 and 4 graphically represent Tables 3 and 4 for the June-September period, only. Dates and locations where rainbow trout and Chinook salmon were observed for the 2000-2010 period are shown in Figures 5 and 6.

### 4.2 Recent surveys: 2001-2010

Since the early summer snorkel survey could not be completed due to high flows in some years (2005, 2006, 2010), the comparative discussion will focus on the September surveys. The number of rainbow trout and Chinook salmon observed for the 2001 to 2010 period were graphed by location for the September surveys (Figures 7 and 8). Rainbow trout were commonly observed in the upper 10 miles of river below the La Grange Dam. This is similar to the distribution of Chinook salmon although Chinook were occasionally seen as far downstream as Hickman Br. (RM 31.5). During the August 10-12 and November 2-4 surveys conducted in 2010, the total numbers of both Chinook and rainbow trout increased from 2007, the last year the late summer surveys were conducted.

The locations sampled since 2001 were the same each year and these surveys were the most comparable. September surveys show rainbow trout counts increased from 2001 to 2005 and were much higher beginning in 2006 (Figure 9). The increase in 2006 and 2010 may be the result of more trout being introduced into the lower river from the La Grange reservoir during the flood control releases occurring during the spring of those years. Chinook salmon counts (Figure 10) in September were comparatively low. Salmon counts were highest in 2010 when 152 and 170 were observed in August and November, respectively.

### 4.3 Other species observed: 1986-2010

The distribution and abundance of non-salmonid fish species observed during the summer snorkel surveys has changed over time. Prior to 1996, more introduced warmwater species were commonly seen with goldfish (Carassius auratus), common carp (Cyprinus carpio), brown bullhead (Ameiurus nebulosus), white catfish (Ameiurus catus), and various sunfish species usually observed (Table 5). After 1996 these species were often absent at upstream sites or observed in lower numbers. The change in species distribution of warmwater species appears to be associated with higher minimum summer flow releases. In addition to O. mykiss and Chinook salmon, other native fish species observed in 2010 were Sacramento sucker, Sacramento pikeminnow, hardhead, Pacific lamprey and riffle sculpin with the non-native species recorded being largemouth bass, smallmouth bass, redear sunfish, and striped bass. The observance of striped bass at R21 (RM 42.9) was unusual. It was the first time this species was seen during the reference snorkel surveys.

Stillwater Sciences

Stillwater Sciences. 2011. March and August 2010 population size estimates of Oncorhynchus mykiss in the Lower Tuolumne River. Prepared for the Turlock Irrigation District and the Modesto Irrigation District by Stillwater Sciences, Berkeley, CA. March.

## SUMMARY

In both early-March and mid-August 2010, population size estimates of Oncorhynchus mykiss were developed in the lower Tuolumne River in accordance with the 3 April 2008 Delegated Order issued by the Federal Energy Regulatory Commission (FERC) implementing elements of a study plan previously developed in coordination with California Dept. of Fish and Game (CDFG), National Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service (USFWS) biologists, and submitted to FERC on 16 July 2007.

Snorkel surveys were conducted during daylight hours from 1 to 8 March and from 17 to 24 August 2010 to estimate O. mykiss population size within the Tuolumne River. In addition to snorkel survey observations of O. mykiss, data for Chinook salmon (O. tshawytscha) and other species was also collected. Snorkel surveys were conducted using a two-phase survey design to sample five different habitat strata (i.e., riffle, run head, run body/tail, pool head, and pool body/tail) found downstream of La Grange Dam at river mile (RM) 51.8 using habitat typing from surveys performed in June 2008 (ending at RM 39.5) and March 2009 (from RM 39.5 down to RM 29.0). The study reaches extended from RM 51.8 to RM 38.4 near a bridge crossing within the 7-11 gravel operation in March and August 2010. A total of 66 of 181 sampling units in the study reach upstream of RM 38.4 were selected for either single pass or multi-pass snorkel surveys in July 2010. A total of 61 sampling units from the same study reach were selected for either single pass or multi-pass snorkel surveys in March 2010.

## O. mykiss population estimates

Based upon the maximum count obtained over all dive passes in each sampled unit, only one young-of-the-year (YOY)/juvenile ( $<150 \mathrm{~mm} \mathrm{FL}$ ) and 13 adult ( $>150 \mathrm{~mm}$ FL) (sum total of 14) O. mykiss were observed in March 2010. During the August 2010 surveys, 313 YOY/juvenile ( $<150 \mathrm{~mm}$ FL) and 324 adult ( $>150 \mathrm{~mm}$ FL) (sum total of 687) O. mykiss were observed along the study reach. Using a bounded counts population estimator (BCE) for the March 2010 survey period, a total of approximately 109 adult $O$. mykiss were present within the study reach (RM 51.8-38.4). No estimate was made for juvenile O. mykiss due to low count of only one individual. Using the same estimator for August 2010 survey period, approximately 2,405 juvenile and 2,139 adult O. mykiss were present within the study reach (RM 51.8-38.4).

The August 2010 juvenile O. mykiss population estimate of 2,405 was lower than the July 2009 estimate of 3,475 and similar to the July 2008 estimate of 2,472 juveniles. However, the summer population estimates are within the $95 \%$ CI for juvenile $O$. mykiss in all three years (2008-2010). The August 2010 adult O. mykiss population estimate of 2,139 was higher than both the July 2009 estimate of 963 and the July 2008 estimate of 643.

## Chinook salmon population estimates

For Chinook salmon encountered during the March and August 2010 snorkel surveys, a maximum count of 577 juveniles ( $<150 \mathrm{~mm}$ FL) were observed during March 2010 within all habitat types along the study reach and a maximum count of 1,028 juvenile Chinook salmon were observed in all habitat types during the August 2010 survey. This corresponded to bounded count population estimates of 6,141 Chinook salmon during the March 2010 surveys, and 6,338 during August 2010. By comparison, the July 2009 juvenile population estimate of 29,389 was much higher and the July 2008 estimate of 2,636 was lower. There were also 14 adult salmon observed in August 2010 as compared with 6 observed in July 2009, and 2 in July 2008.

## Other species

A combination of native minnows (hardhead and Sacramento pikeminnow), along with native Sacramento sucker accounted for approximately $97 \%$ of non-salmonid fish observed for both the March and August sampling periods, with very low counts of non-native centrarchid species (largemouth bass, smallmouth bass) observed. Native minnows and suckers were found throughout the reaches in both sampling periods.

## Relationship between Temperature and O. mykiss habitat use

To test the hypothesis that the summertime distribution of suitable habitat by observed life stages of $O$. mykiss is related to ambient river water temperature, water temperature data from thermographs deployed in the Tuolumne River were compared to juvenile and adult O. mykiss density from the August 2010 survey along the study reach. The data show that temperatures increased in the downstream direction, from $12.0^{\circ} \mathrm{C}\left(53.6^{\circ} \mathrm{F}\right)$ to $17.8^{\circ} \mathrm{C}\left(64.1^{\circ} \mathrm{F}\right)$ (maximum weekly average temperature [MWAT]), and that O. mykiss density of both adult and juveniles generally decreased along this same gradient. Although the longitudinal distribution of O. mykiss was similar for both the March and August surveys, the lower number of O. mykiss observations in March 2010, coupled with low water temperatures (maximum observed $<14.5^{\circ} \mathrm{C}\left[58.1^{\circ} \mathrm{F}\right]$ ) precluded any meaningful associations with temperature for the March 2010 surveys.

## O. Mykiss habitat use at Restoration sites

A second hypothesis that habitat use by O. mykiss juveniles and adults observed in the Tuolumne River occurred at the same density in both restored and nearby reference sites was tested based on observed densities of $O$. mykiss juveniles and adults in habitat types (riffle, run head, and pool head) common to both groups in the August survey. For juveniles, this comparison showed riffle habitat use at upstream restoration sites was slightly greater than that of other riffle habitats. Juvenile habitat use within run head habitats was similar or reduced at the restoration sites in comparison to reference sites, with relatively low use of pool head habitat. For adults, this comparison showed a potential reduction of habitat use of riffle habitat at restoration sites, with similar use of run head habitat, and insufficient data for a comparison of pool head habitats.

## Comparison with August 2010 Reference Survey Results

A comparison was made of $O$. mykiss and juvenile Chinook data collected during the August 2010 survey to "reference count", snorkel survey data collected during August 2010 by TID/MID. The comparison shows a similar longitudinal trend, with overall densities decreasing in the downstream direction for both species. Along the study reach common to both surveys, a total of 195 O. mykiss juveniles and 73 adults were observed in the August reference count snorkel survey, while 210 juveniles and 253 adults were observed in the August BCE survey. A total of 142 juvenile Chinook were seen in the August reference survey with 889 seen in the August 2010 BCE survey.

## 1 INTRODUCTION

Routine fisheries monitoring surveys for the Don Pedro Project (FERC Project No. 2299) by the Turlock Irrigation District (TID) and Modesto Irrigation District (MID) have long documented the presence of Oncorhynchus mykiss in the lower Tuolumne River (TID/MID 2005). Summer snorkel surveys, conducted in most years since 1988, have documented an increased O. mykiss presence and relative abundance that is associated with the more consistent and higher summer flows provided since 1997 (TID/MID 2008).

On 19 March 1998, the National Marine Fisheries Service (NMFS) first listed the Central Valley steelhead as threatened under the Endangered Species Act (ESA). After several court challenges, NMFS issued a new final rule relisting the Central Valley steelhead on 5 January 2006 (71 FR 834). In a separate process resulting from terms of the 1996 FERC license amendment for the Project, NMFS staff provided input to a draft limiting factors analysis for Tuolumne River salmonids (Mesick et al. 2007) and included recommendations for developing abundance estimates, habitat use surveys, and anadromy determination of resident $O$. mykiss. These recommendations were conceptually used to develop the Districts’ FERC Study Plan (TID/MID 2007), which was the subject of a 3 April 2008 FERC Order. As part of the Order, the Districts were required to conduct population estimate surveys in winter (February/March) and summer (June/July), with the first surveys starting in summer 2008 to determine $O$. mykiss population abundance by habitat type.

The Districts first submitted a detailed O. mykiss population estimate study plan (Stillwater Sciences 2008a) to FERC on 3 July 2008 to provide information on the abundance and habitat requirements within the lower Tuolumne River. A report on the July 2008 population size estimate (Stillwater Sciences 2008b) was submitted as part of the Districts’ 2008 annual report to FERC (TID/MID 2009). An updated study plan (Stillwater Sciences 2009) was prepared in 2009 for the population estimate surveys and is attached to this report as Appendix A. In addition to providing data to develop population size estimates under current conditions, the study plan examined the following hypotheses:

Hypothesis 1: Summertime distribution of suitable habitat by observed life stages of $O$. mykiss is related to ambient river water temperature.

Hypothesis 2: Habitat use by O. mykiss juveniles and adults observed in the Tuolumne River occurs at the same density in both restored and nearby reference sites.

The $O$. mykiss snorkel surveys employed a two-phase sampling approach for the development of a reach-wide population estimate (Hankin and Mohr 2001) in the lower Tuolumne River. Survey sites were selected using a stratified random sampling approach, where the strata were major habitat types. In both March and August 2010, the overall sampling "universe" from which sampling strata were delineated extended from near La Grange Dam at river mile (RM) 51.8 to RM 38.4 at a bridge crossing within the 7-11 Materials, Inc. gravel operation (Figure 1). This reach coincides with the downstream areas where O. mykiss were observed (Riffle 31 at RM 38.0) during the August 2010 "reference count" snorkel surveys (Kirihara 2010).

The two-phase stratified sampling design involved snorkeling pre-selected sampling units (e.g., riffle, run, pool, etc.) multiple times in order to quantify the variance associated with density and subsequent population estimates. As in a typical Phase I sampling approach, primary snorkel surveys (Edmundson et al. 1968, Hankin and Reeves 1988, McCain 1992, Dolloff et al. 1996)
were conducted across a subset of the all sampling units. In Phase II, approximately 20-70\% of each habitat type sampled was randomly selected for replicated surveys by repeated dive counts.

The methods presented by Stillwater Sciences (2009) discussed using a combined approach of both repeated dive counts and electrofishing. Current ESA permit restrictions for NMFS Section 10(a)(1)(A) permit No. 1282 (Stillwater) did not allow sufficient incidental take to conduct the second-phase surveys using electrofishing. Consequently, the surveys used only snorkel surveys, as provided for in the 2007 study plan and identified in letters provided by the Districts to FERC dated 3 July 2008 and 31 March 2009.

## 2 METHODS

### 2.1 Habitat Characterization

### 2.1.1 Habitat mapping

Habitat maps were compiled from an analysis of past habitat surveys, historical and more recent aerial photographs, and field surveys conducted in 2008, with results superimposed within a geographic information system (GIS). Field maps for the March and August 2010 BCE snorkel surveys were created using an orthorectified aerial photo and accompanying Light Detection and Ranging (LiDAR) topographic data from 21 September 2005 recorded at river flows of 321 cfs. Preliminary sampling unit boundaries of common habitat features (pools, riffles, and runs) were estimated from the LiDAR and bathymetric data between RM 52-38 within GIS by calculating locations corresponding to major water depth transitions (Table 2-1).

Table 2-1. Coarse-scale habitat types used during snorkel surveys.
$\left.\begin{array}{c|c|c}\hline \begin{array}{c}\text { Habitat } \\ \text { type }\end{array} & \text { Description }{ }^{\text {a }} & \begin{array}{c}\text { Approximate } \\ \text { depth }\end{array} \\ \hline \text { Riffle } & \begin{array}{c}\text { Shallow with swift flowing, turbulent water. Partially } \\ \text { exposed substrate dominated by cobble or boulder. } \\ \text { Gradient moderate (less than 4\%). }\end{array} & 0-4 \mathrm{ft} \\ \hline \text { Run } & \begin{array}{c}\text { Fairly smooth water surface, low gradient, and few } \\ \text { flow obstructions. Mean column velocity generally } \\ \text { greater than one foot per second (fts }\end{array} \\ \hline \text { Pool. }\end{array} \quad \begin{array}{c}\text { Slow flowing, tranquil water with mean column water } \\ \text { velocity less than } 1 \mathrm{fts}^{-1} .\end{array}\right]>10 \mathrm{ft}$.
a Major habitat types determined based upon observed hydraulic conditions (McCain 1992, Thomas and Bovee 1993, Cannon and Kennedy 2003)

As an initial validation of these coarse scale habitat types, we compared the habitat types mapped in July 2008 (Appendix B) with previous habitat type maps (Appendix C) developed by McBain and Trush (2004) between 1999-2001 on a base-layer map corresponding to a wetted perimeter of 622 cfs flown on 20 May 20 1991. Appendix C shows major habitat types (i.e., riffle, run, pool) encountered during the 1999-2001 surveys along with past and planned gravel introduction locations included in the Tuolumne River Coarse Sediment Management Plan (McBain and Trush 2004).

In general, habitat typing shown by McBain and Trush (Appendix C) indicates larger proportions of "pool" habitat types than those determined during this effort (Appendix B), which reserved the pool habitat designation for water depths greater than 10 ft . Additionally, because $O$. mykiss tend to congregate at transitions between habitat types, Appendix B shows a further division of pool and run body habitats into smaller, transitional habitat sampling units (pool head, pool tail, run head, and run tail) based upon location of slope channel slope break at the upstream and downstream end of the unit. For both the March and August 2010 surveys, pool tail and run tail habitats were consolidated into corresponding upstream pool body or run body habitat. This action was based on low use of the pool tail and run tail habitats as discrete sampling units in prior surveys (July 2008 and March 2009) and results in a reduced number of sampling units having low potential for use by salmonids available for habitat selection, thereby increasing the number of sampling units having a higher potential use, while not eliminating them from the area surveyed (see Section 2.2.1 for a complete description of sampling unit selection).

### 2.1.2 Habitat data collection

Float surveys were conducted in July 2008 and February 2009 to further refine and validate the preliminary habitat maps (Appendix B) described above at flows of approximately 106 cfs and 168 cfs , respectively. In addition to refining the locations and sizes of potential habitat sampling units, we collected habitat data (Table 2-2) at several locations within each sampling unit. Starting at upstream end of the study reach just downstream of La Grange Dam (Figure 1), habitat units were assigned a natural sequence order (NSO), a number, beginning with NSO 001, and incremented this identifier at each habitat transition (e.g., NSO 001 pool head, NSO 002 pool body, etc). The upstream and downstream end of each unit was located and marked on field maps, the location recorded with a handheld GPS unit, and labeled with flagging indicating the date, unit number, and habitat type.

Table 2-2. Habitat data collected at each unit.

| Parameter | Method | Metric/Descriptor | Method <br> reporting <br> limit |
| :--- | :---: | :---: | :---: |
| Natural Sequence Order <br> (NSO - Habitat unit \#) | N/A | NSO-1, NSO-2, NSO-3, .. | N/A |
| Latitude/Longitude | Handheld GPS <br> receiver | UTM | $\mathrm{N} / \mathrm{A}$ |
| Habitat type | Visual estimation | See Table 2-1 | $\mathrm{N} / \mathrm{A}$ |
| Average unit width | Horizontal distance | Meters (feet) (measured at <br> multiple transects) | $0.01 \mathrm{~m} \mathrm{(0.1ft)}$ |
| Average unit length | Horizontal distance | Meters (feet) | $0.01 \mathrm{~m} \mathrm{(0.1ft)}$ |
| Maximum/minimum depth | Vertical distance | Meters (feet) | $0.15 \mathrm{~m} \mathrm{(0.5ft)}$ |
| Bed substrate composition | Visual estimation | Bedrock, boulder, cobble, <br> gravel, organic, sand, silt | $10 \%$ |
| Cover type | None, boulder, cobble, <br> IWM, bedrock ledges, <br> overhead vegetation, <br> aquatic vegetation | $10 \%$ |  |

Note that although the base layer of the 2009 habitat maps corresponds to a 2005 air photo at flows of 321 cfs, in order to provide a more accurate channel edge boundary for the March and July 2009 surveys, the channel edge of the habitat unit boundaries shown in Appendix B correspond to a wetted perimeter of 230 cfs previously digitized from air photos taken in 1986-87 and later refined to adjust for channel migration. The average daily flow during the March 2010 sampling was 224 cfs, and the average daily flow during the August 2010 sampling was 293 cfs. Because the estimated wetted perimeter of the habitat unit boundaries did not vary more than a few feet in most cases at these two flows, the channel edge boundary for 230 cfs was used for both the March and August 2010 surveys. For each habitat unit shown, habitat unit length and width were subsequently determined in GIS. Appendix D shows accompanying field habitat data collected in all habitat units mapped, including maximum depth and average width (usually at $1 / 3$ and $2 / 3$ of the unit's length), bed substrate composition, and instream cover type.

### 2.2 Snorkel Surveys

### 2.2.1 Study design and survey unit selection

After habitat typing and collecting habitat data in all units, a subset of units of each habitat strata was selected for single-pass snorkel surveys. The survey units were selected to balance the habitat sampling unit replication, total available number of units to draw from, coverage of at least $10 \%$ of the total length of a given habitat type, as well as sampling effort. The selection process involved random selection of one of the most upstream units of each habitat type, followed by a systematic uniform sampling of the remaining units in the study reach. After the first dive pass was completed, a tab was then pulled to determine if the unit was included in the second phase of sampling.

For the March 2010 surveys, a subset of 6-7 units was selected for each of the 5 habitat types, with the exception of the riffle habitat type for which 10 units were selected to capture habitat use at particular gravel augmentation projects (Table 2-3). In August 2010, a subset of 6-7 sampling units was selected from each of 5 habitat types (Table 2-4), with representative riffle habitats corresponding to restoration sites at some locations.

Table 2-3. Sample unit selection and survey count for March 2010.

| Habitat | Phase I dives |  | Phase II survey |  |
| :--- | :---: | :---: | :---: | :---: |
|  | Initial <br> units | Passes | Repeat <br> units | Passes |
| Riffle | 10 | 1 | 3 | 2 |
| Pool head | 6 | 1 | 3 | 2 |
| Pool body /tail | 6 | 1 | 3 | 2 |
| Run head | 7 | 1 | 3 | 2 |
| Run body /tail | 7 | 1 | 3 | 2 |
| Total | $\mathbf{3 6}$ |  | $\mathbf{3 0}$ |  |

Table 2-4. Sample unit selection and survey count for August 2010.

| Habitat | Phase I dives |  | Phase II survey |  |
| :--- | :---: | :---: | :---: | :---: |
|  | Initial <br> units | Passes | Repeat <br> units | Passes |
| Riffle | 7 | 1 | 3 | 2 |
| Pool head | 6 | 1 | 3 | 2 |
| Pool body /tail | 6 | 1 | 3 | 2 |
| Run head | 6 | 1 | 3 | 2 |
| Run body /tail | 6 | 1 | 3 | 2 |
| Total | $\mathbf{3 1}$ |  | $\mathbf{3 0}$ |  |

### 2.2.2 Snorkel data collection

Snorkel surveys were conducted during daylight hours from 1 to 8 March and 17 to 24 August 2010, respectively. A two-phase survey design was used to survey the various riffle, run, and pool strata. For the first phase, single-pass dive surveys were conducted by a four-person team. Sampling units were sampled from downstream to upstream in dive lanes using a zigzag pattern, passing fish and allowing them to escape downstream of the diver. If fish were observed to escape upstream, the diver took care to avoid counting these individuals twice. Divers recorded the type, length, and number of fish (Table 2-5). Total lengths were estimated in 50 mm size ranges (called "bins") using markings on dive slates to correct for underwater size distortion.

Table 2-5. Fish data collected within each unit during snorkel surveys.

| Parameter | Method | Metric/Descriptor | Method reporting <br> limit |
| :--- | :---: | :---: | :---: |
| Date; start and end time | N/A | Day/month/year; <br> hour/minute | N/A |
| Number of individuals | Visual estimation | Number | 1 |
| Fish length | Visual estimation | Millimeter | 50 mm bins |

The second phase of sampling required the collection of repeat dive countss and fish size data during each of two subsequent passes through the selected habitat units. These data were later used to statistically expand the dive counts to total population estimates for each habitat type. The Phase 2 dive pass replication was established at 2 passes in 2009 surveys to reduce sampling effort within particular sampling units while increasing the overall sample unit coverage (Stillwater 2010). Lastly, the occurrence of other non-salmonid native and non-native fish species was recorded as presence/absence and abundance.

### 2.3 Water Quality and Flow

At fish sampling locations, in addition to noting the type, length, and number of fish (Section 2.2), we collected spot measurements of in situ water quality data (temperature, dissolved oxygen, and conductivity) using a pre-calibrated multi-probe (YSI 85, Yellow Springs Instruments, Yellow Springs, OH) (Table 2-6). Dissolved oxygen (DO) probes were recalibrated each day and checked for accuracy in the laboratory against DO concentrations measured in
aerated tap water. Changes in underwater visibility were monitored horizontally using a Secchi disk oriented both toward and away from the sun. Daily average flow data for each day were obtained from the stream gage below the La Grange powerhouse at RM 51.8 (USGS No. 11289650).

Table 2-6. Water quality data collected during snorkel surveys.

| Parameter | Method | Metric/Descriptor | Method reporting <br> limit |
| :--- | :---: | :---: | :---: |
| Temperature | EPA 170.1 | ${ }^{\circ} \mathrm{C}$ | $0.1^{\circ} \mathrm{C}$ |
| Dissolved oxygen | SM 4500-O | $\mathrm{mg} / \mathrm{L}$ | $0.01 \mathrm{mg} / \mathrm{L}$ |
| Conductivity | SM 2510A | umhos $/ \mathrm{cm}$ | $1.0 \mathrm{umhos} / \mathrm{cm}$ |
| Visibility | Secchi depth | meters (feet $)$ | $0.01 \mathrm{~m}(0.1 \mathrm{ft})$ |

### 2.4 Water and Air Temperatures

From Spring 1987 to present, TID/MID has collected water temperature data from various locations in the lower Tuolumne River using recording thermographs (Hobo Pro V2 thermographs, OnSet Computer Corporation, Bourne, MA). The thermographs measured and stored water temperature data at one-hour intervals, with data downloads ocurring at least twice a year.

Water temperature data collection during March and August 2010 also included spot measurements taken during snorkel surveys. The measurements were recorded over the course of the day as divers moved further downstream; as such, it was anticipated that these water temperatures would not be as representative as hourly thermograph recordings. The data do provide a general description of relative temperature conditions during dive surveys, however.

Regional air temperature data were obtained from the National Weather Service (NWS) station at Modesto Airport near RM 18. Water and air temperature data for the February through March, and July through August 2010 periods are presented in this report (Figures 2a and 2b).

### 2.5 Data analysis

### 2.5.1 Bounded counts population estimate

Water quality and fish observation counts were summarized by habitat unit type with initial density estimates calculated based upon the area searched within each habitat unit sampled. In addition to comparisons of fish density between habitat types, the density estimates and uncertainties were propagated across the unsampled areas for an overall reach-wide population estimate.

Population estimates were made for each stratum and size class using the general methods of Hankin and Mohr (2001). For units receiving multiple dives, the bounded counts formulae are used to produce an estimate of the unit population and an estimate of the variance of this estimate. Specifically, when there are $r$ passes, and the counts of these are sorted in increasing order as $m_{1} \leq m_{2} \leq \ldots \leq m_{r}$, the population is estimated as
$\tilde{y}_{B}=m_{r}+\left(m_{r}-m_{r-1}\right)$,
and the mean squared error of this is estimated as
$\operatorname{MSE}\left(\tilde{y}_{B}\right)=\left(m_{r}-m_{r-1}\right)^{2}$.

The total population of multiply dived units is estimated as the sum of the bounded-counts estimates for the individual units. The total population of the survey region is estimated by expanding this, first to all dived units (singly or multiply dived) on the basis of mean dive counts, and then to all units (dived or undived) on the basis of area. An estimator of the variance of this is constructed from estimates of the mean-squared errors of the bounded-counts estimates for the multiply dived individual units, and the variance of the bounded-counts estimates around their common mean. The final formulae are included in Hankin and Mohr (2001). A nominal confidence interval for each stratum and size class was calculated formally as
$\hat{Y} \pm 1.96 \sqrt{\hat{V}}$, where $\hat{Y}$ and $\hat{V}$ are the mean and variance estimates, except that the lower bound of this interval was "trimmed" to the number of fish actually observed.

### 2.5.2 Comparisons with August 2010 Reference Count snorkel surveys

Data collected during the August 2010 snorkel surveys (17-24 August) were compared to reference count snorkel survey data collected during 10-12 August 2010 (Kirihara 2010). Although the sampled areas of these surveys differ, these data were collected only a few weeks prior to the data collected for this report, allowing for a general comparison of presence/absence and the relative proportions of larger and smaller size classes of $O$. mykiss and Chinook salmon in sampling units sampled during both surveys. Further, although TID/MID has sampled the same locations since 2001, we limit our comparison to the August 2010 data as these are the most directly comparable. There were no reference count survey data available for comparison with the March 2010 snorkel surveys.

## 3 RESULTS

### 3.1 Habitat Characterization

### 3.1.1 March 2010

For the total reach surveyed in March 2010 (RM 51.8-38.4), "run body/tail" habitat type occupied the greatest length of channel along the study reach, followed by riffles (Table 3-1). The "pool body/tail" habitat type, while less abundant than other habitat types (e.g., run head), occupied the third greatest length of channel. Other transitional habitat types (e.g., run head and pool head) accounted for only 4.8 \% of the total reach length. Habitat maps and data for the entire study reach are shown in Appendices B and D. The longitudinal distribution of the area of each of the major habitat types within bins of 2 river miles is shown in Figure 3. Figure 4a presents the distribution of each of the major habitat types sampled in March 2010.

Table 3-1. Summary of habitat types from RM 51.8 to 38.4, March and August 2010.

| Habitat type | Count | \% by count | Total length <br> (ft) | Total length <br> (mi) | \% reach <br> length | Area <br> (ft ${ }^{\mathbf{}}$ ) |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| Riffle | 40 | 22.1 | 15,271 | 2.89 | 21.4 | $1,281,867$ |
| Pool head | 7 | 3.9 | 712 | 0.13 | 1.0 | 61,958 |
| Pool body/tail | $11 / 7$ | 9.9 | 9,238 | 1.75 | 12.9 | $1,143,736$ |
| Run head | 38 | 21.0 | 2,712 | 0.51 | 3.8 | 253,658 |
| Run body/tail | $42 / 36$ | 43.1 | 43,423 | 8.22 | 60.9 | $4,449,862$ |
| Total | $\mathbf{1 8 1}$ | $\mathbf{1 0 0 . 0}$ | $\mathbf{7 1 , 3 5 6}$ | $\mathbf{1 3 . 5 1}$ | $\mathbf{1 0 0 . 0}$ | $\mathbf{7 , 1 9 1 , 0 8 1}$ |

### 3.1.2 August 2010

The total reach surveyed in August 2010 (RM 51.8-34.8), was identical to the reach surveyed in March 2010 and therefore contains the same overall distribution of habitat types as shown in Table 3-1. Habitat maps and data for the entire study reach are shown in Appendices B and D. The longitudinal distribution of the area of each of the major habitat types within equal segments of 2 river miles is shown in Figure 3. Figure 4b presents the distribution of each of the major habitat types sampled in August 2010.

### 3.2 Water Quality and Flow

As water quality data were collected exclusively within units chosen for snorkel survey, data are presented by river mile, rather than by sampling unit, or summarized for the entire reach (Table 3-2 and Table 3-3). Water quality data for sampling units selected for snorkel surveys are shown in Appendix E.

Because of the strong influence of ambient air temperatures (Sullivan et al. 1990), temperatures of water released from the cold water pool of Don Pedro Reservoir increase in a downstream direction for both the spot measurements (Table 3-3) and in the continuous thermograph record during both the March and July survey periods (Appendix F). Note that the water temperature ranges shown in Table 3-2 and Table 3-3 represent changes over the course of the sampling day, and do not include nighttime temperatures or lows that are shown at representative thermograph locations in Appendix F.

### 3.2.1 March 2010

Daily average flow during the March 2010 survey period was 223 cfs. In general, dissolved oxygen concentration was high due to the low water temperatures. Horizontal visibility was reduced at the most downstream location due to local turbidity sources.

Table 3-2. Range of water quality data collected at snorkel sites during fish surveys in March 2010.

| River miles | Sample date | Flow <br> $(\mathbf{c f s})^{1}$ | Water temp ${ }^{\circ} \mathrm{C}$ <br> $\left[{ }^{\circ} \mathbf{F}\right]$ | DO <br> $(\mathbf{m g} / \mathrm{L})$ | Horizontal <br> visibility <br> $(\mathbf{f t})$ | Specific <br> conductivity <br> $(\mathbf{u S} / \mathbf{c m})$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $51.6-50.8$ | 1 March | 224 | $10.6-11.3$ <br> $[51.1-52.3]$ | $10.6-12.4$ | 13.5 | $29.1-30.5$ |
| $50.6-49.7$ | 2 March | 223 | $10.6-11.0$ <br> $[51.1-51.8]$ | $10.6-11.5$ | 17 | $28.1-32.5$ |

${ }^{1}$ Daily average flow data are measured from the stream gauge below La Grange powerhouse at RM 51.8 (USGS No. 11289650).

### 3.2.2 August 2010

Daily average flow during the August 2010 survey period ranged from 287-295 cfs. In general, there were only relatively small variations in water quality parameters at this flow range. Horizontal and vertical visibility indicated very low turbidity during the survey period.

Table 3-3. Range of water quality data collected at snorkel sites during fish surveys in J uly 2009.

| River miles | Sample date | Flow <br> $(\mathbf{c f s})^{\mathbf{1}}$ | Water temp ${ }^{\circ} \mathbf{C}$ <br> $\left[{ }^{\circ} \mathbf{F}\right]$ | DO <br> $(\mathbf{m g} / \mathbf{L})$ | Horizontal <br> visibility <br> (ft) | Specific <br> conductivity <br> $(\mathbf{u S / c m})$ |

[^7]
### 3.3 Water and Air Temperature

The daily average water temperature for all thermographs and the daily minimum, maximum, and average air temperature (from the NWS station at the Modesto Airport) are shown in Appendix F. The range of daily averages, instantaneous maximum temperature, maximum weekly average temperature (MWAT), and the seven-day average of daily maximum temperature (7dayMAX) for the 1-8 March and 17-24 August study periods was determined, and all three metrics for both periods showed a similar trend of increasing in the downstream direction. The MWAT is the seven-day rolling average of average daily temperatures, and describes ambient water temperature conditions over the previous week. It is a standard used in water quality studies and total maximum daily load (TMDL) estimations of allowable temperature. The 7dayMAX is the seven-day rolling average of the daily maximum temperatures, and is a potentially more accurate indicator of conditions affecting survival and growth of salmonids (Sullivan et al. 2000, Stillwater Sciences 2002).

### 3.3.1 March 2010

During the March 2010 survey period, water temperature data collected by thermographs followed similar trends to spot temperature data collected during snorkel surveys, showing an increase in the downstream direction (Table 3-4). Along the study reach, the MWAT increased from $10.6^{\circ} \mathrm{C}\left(51.1^{\circ} \mathrm{F}\right)$ at Riffle A7 to $12.1^{\circ} \mathrm{C}\left(53.7^{\circ} \mathrm{F}\right)$ at the Ruddy Gravel site (Table $\left.3-4\right)$. The 7dayMAX temperature ranged from $11.1^{\circ} \mathrm{C}\left(52.0^{\circ} \mathrm{F}\right)$ at the Riffle A7 location to $13.2^{\circ} \mathrm{C}\left(55.7^{\circ} \mathrm{F}\right)$ at the Ruddy Gravel site. The hourly, mean weekly average (MWAT), and 7dayMAX water temperatures for Riffle A7 (RM 50.8), Riffle 13B (RM 45.5), Roberts Ferry Bridge (RM 39.6), and Ruddy Gravel (RM 36.5) from 1 February to 31 March 2010 are presented graphically in Appendix F.

Table 3-4. Maximum weekly average temperature, seven-day average of daily maximum temperatures, and instantaneous maximum temperatures recorded by thermographs in the survey reach of the lower Tuolumne River during March 2010.

| Monitoring location | RM | MWAT ${ }^{\mathbf{o}} \mathbf{C}\left[{ }^{\circ} \mathbf{F}\right]$ <br> (week ending) | 7dayMAX ${ }^{\circ} \mathbf{C}\left[{ }^{\circ} \mathbf{F}\right]$ <br> (week ending) | Instantaneous <br> maximum ${ }^{\circ} \mathbf{C}\left[{ }^{\circ} \mathbf{F}\right]$ <br> (date) |
| :--- | :---: | :---: | :---: | :---: |
| Riffle A7 | 50.8 | 10.6 [51.1] (2 March) | 11.1 [52.0] (2 March) | 11.4 [52.5] (1 March) |
| Riffle 13B | 45.5 | 11.3 [52.3] (7 March) | 12.2 [54.0] (6 March) | 12.7 [54.8] (1 March) |
| Roberts Ferry Bridge ${ }^{1}$ | 39.6 | 11.8 [53.3] (7 March) | 12.8 [55.0] (7 March) | 13.7 [56.7] (7 March) |
| Ruddy Gravel | 36.5 | 12.1 [53.7] (7 March) | 13.2 [55.7] (7 March) | 14.2 [57.5] (7 March) |

Note: Thermographs used have a reported error of $\pm 0.2^{\circ} \mathrm{C}$.
${ }^{1}$ Thermograph located approximately 0.75 miles upstream of bridge.

The average daily Modesto Airport air temperatures over the study period ranged from 8.3 to 12.8 ${ }^{\circ} \mathrm{C}\left(47.0\right.$ to $\left.55.0^{\circ} \mathrm{F}\right)$ with a high temperature of $18.9^{\circ} \mathrm{C}\left(66.0^{\circ} \mathrm{F}\right)$ (Table 3-5). The warmest day of March occurred after the study period on 17 March with an average daily temperature of $17.8^{\circ} \mathrm{C}$ $\left(64.0^{\circ} \mathrm{F}\right)$ (Figure 2a) and a daily high temperature of $23.9^{\circ} \mathrm{C}\left(75.0^{\circ} \mathrm{F}\right)$. The highest daily maximum temperature in March occurred on 28 March with a reading of $26.1^{\circ} \mathrm{C}\left(79.0^{\circ} \mathrm{F}\right)$.

Table 3-5. Daily average, minimum, and maximum air temperature recorded at the NWS station at the Modesto Airport during the March 2010 snorkeling study period.

| Date | Average air <br> temperature ${ }^{\mathbf{o}} \mathbf{C}\left[{ }^{\circ} \mathbf{F}\right]$ | Minimum air <br> temperature ${ }^{\circ} \mathbf{C}\left[{ }^{\circ} \mathbf{F}\right]$ | Maximum air <br> temperature ${ }^{\circ} \mathbf{C}\left[{ }^{\circ} \mathbf{F}\right]$ |
| :---: | :---: | :---: | :---: |
| 1 March 2009 | $12.8[55]$ | $6.7[44]$ | $18.3[65]$ |
| 2 March 2009 | $11.7[53]$ | $7.8[46]$ | $15.0[59]$ |
| 3 March 2009 | $8.9[48]$ | $6.7[44]$ | $11.1[52]$ |
| 4 March 2009 | $10.0[50]$ | $5.6[42]$ | $14.4[58]$ |
| 5 March 2009 | $8.3[47]$ | $2.2[36]$ | $13.9[57]$ |
| 6 March 2009 | $12.8[55]$ | $8.3[47]$ | $17.2[63]$ |
| 7 March 2009 | $12.2[54]$ | $5.0[41]$ | $18.9[66]$ |
| 8 March 2009 | $10.0[50]$ | $5.6[42]$ | $14.4[58]$ |

Hourly water temperature for several monitoring stations along the length of the study reach and daily air temperature from the Modesto Airport station was compared (Figure 2a). With flow being stable throughout period, Figure 2a shows that at the upstream-most monitoring station, water and air temperature are more independent of each other than at thermographs located farther downstream. That is, water temperature becomes more influenced by air temperature in the downstream direction, with water and air temperature peaks and troughs occurring at the same times of day at the downstream monitoring site at Roberts Ferry Bridge (RM 39.6).

### 3.3.2 August 2010

During the August 2010 survey period, water temperature data collected by thermographs followed similar trends to spot temperature data collected during snorkel surveys, which showed a general increase in the downstream direction (Table 3-6). Along the study reach, the MWAT increased from $12.0^{\circ} \mathrm{C}\left(53.6^{\circ} \mathrm{F}\right)$ at Riffle A7 to $17.8^{\circ} \mathrm{C}\left(64.1^{\circ} \mathrm{F}\right)$ at Ruddy Gravel (Table 3-6). The 7dayMAX temperature ranged from $13.3^{\circ} \mathrm{C}\left(55.9^{\circ} \mathrm{F}\right)$ at the Riffle A7 location to $19.2^{\circ} \mathrm{C}$ ( $66.6^{\circ} \mathrm{F}$ ) at the Roberts Ferry Bridge. The hourly, mean weekly average (MWAT), and 7dayMAX water temperatures for Riffle A7 (RM 50.8), Riffle 13B (RM 45.5), Roberts Ferry Bridge (RM 39.6), and Ruddy Gravel (RM 36.5) from 1 July to 31 August 2010 are presented graphically in Appendix F.

Table 3-6. Maximum weekly average temperature, seven-day average of daily maximum temperatures, and instantaneous maximum temperatures recorded by thermographs in the survey reach of the lower Tuolumne River during August 2010.

| Monitoring location | RM | MWAT ${ }^{\circ} \mathrm{C}\left[{ }^{\circ} \mathrm{F}\right]$ (week ending) | 7dayMAX ${ }^{\circ} \mathrm{C}\left[{ }^{\circ}{ }^{\circ}\right.$ F] (week ending) | Instantaneous maximum ${ }^{\circ} \mathrm{C}$ [ ${ }^{\circ} \mathbf{F}$ ] <br> (date) |
| :---: | :---: | :---: | :---: | :---: |
| Riffle A7 | 50.8 | 12.0 [53.6] (19 August) | 13.3 [55.9] (19 August) | 13.4 [56.0] (17 August) |
| Riffle 13B | 45.5 | 14.5 [58.1] (18 August) | 16.5 [61.7] (18 August) | 16.7 [62.0] (17 August) |
| Roberts Ferry Bridge ${ }^{1}$ | 39.6 | 17.1 [62.7] (19 August) | 18.5 [65.3] (18 August) | 18.7 [65.6] (17 August) |
| Ruddy Gravel | 36.5 | 17.8 [64.1] (19 August) | 19.2 [66.6] (19 August) | 19.5 [67.0] (17 August) |

Note: Thermographs used have a reported error of $\pm 0.2^{\circ} \mathrm{C}$.
1 Thermograph located approximately 0.75 miles upstream of bridge.

The average daily Modesto Airport air temperatures over the study period ranged from 21.7 to $27.8^{\circ} \mathrm{C}\left(71.0\right.$ to $\left.82.0^{\circ} \mathrm{F}\right)$ with a high temperature of $38.9^{\circ} \mathrm{C}\left(102{ }^{\circ} \mathrm{F}\right)$ (Table 3-7). The warmest day of August occurred just after the study period on 25 August with an average daily temperature of $30.0^{\circ} \mathrm{C}\left(86^{\circ} \mathrm{F}\right)$ and a daily high temperature of $41.7^{\circ} \mathrm{C}\left(107^{\circ} \mathrm{F}\right)$ (Figure 2b).

Table 3-7. Daily average, minimum, and maximum air temperature recorded at the NWS station at the Modesto Airport during the August 2010 snorkeling study period.

| Date | Average air <br> temperature ${ }^{\circ} \mathbf{C}\left[{ }^{\circ} \mathbf{F}\right]$ | Minimum air <br> temperature ${ }^{\circ} \mathbf{C}\left[{ }^{\circ} \mathbf{F}\right]$ | Maximum air <br> temperature ${ }^{\circ} \mathbf{C}\left[{ }^{\circ} \mathbf{F}\right]$ |
| :---: | :---: | :---: | :---: |
| 17 August 2010 | $24.4[76.0]$ | $16.1[61.0]$ | $32.8[91.0]$ |
| 18 August 2010 | $22.8[73.0]$ | $14.4[58.0]$ | $31.1[88.0]$ |
| 19 August 2010 | $24.4[76.0]$ | $14.4[58.0]$ | $33.9[93.0]$ |
| 20 August 2010 | $25.6[78.0]$ | $16.1[61.0]$ | $34.4[94.0]$ |
| 21 August 2010 | $21.7[71.0]$ | $14.4[58.0]$ | $28.9[84.0]$ |
| 22 August 2010 | $21.7[71.0]$ | $12.8[55.0]$ | $30.0[86.0]$ |
| 23 August 2010 | $24.4[76.0]$ | $14.4[58.0]$ | $34.4[94.0]$ |
| 24 August 2010 | $27.8[82.0]$ | $16.1[61.0]$ | $38.9[102.0]$ |

Hourly water temperature for several monitoring stations along the length of the study reach and daily air temperature from the Modesto Airport station was compared (Figure 2b). High flows through July kept water temperatures relatively low with little variability. Flow reductions in early August to approximately 300 cfs, shows a slight increase in variability among the temperature stations, but a continuation of relatively low temperatures, with a reduced influence of air temperature at thermographs located farther downstream (Figure 2b).

### 3.4 Snorkel Surveys

### 3.4.1 March 2010

### 3.4.1.1 O. mykiss observations

During the March 2010 survey period, divers observed 15 O. mykiss ranging from $0-600 \mathrm{~mm}$ ( 50 mm size bins) based upon maximum counts of all dive passes in each sampling unit (Table 3-8, Table 3-9 and Appendix G). These included one fish classified as a juvenile in the 50-99 mm size category, with the other 14 observed in the adult ( $>150 \mathrm{~mm}$ ) size classes (Table 3-8 and Table 3-9). The $O$. mykiss were observed in 9 different sampling units from RM 51.6 to RM 38.5. The $O$. mykiss were observed in all habitat types, with the exception of the "Run body/tail" habitat, with the juvenile observation in a pool head habitat unit at RM 51.6 (Table 3-8 and Table 3-9).

Table 3-8. Maximum count of O. mykiss by sampling unit, March 2010 (data are divided into 50 mm total length size classes).

| RM | Sampling Unit | Habitat | $\begin{gathered} \hline \text { Multiple } \\ \text { pass } \\ \text { survey } \\ (\mathrm{Y} / \mathrm{N}) \\ \hline \end{gathered}$ | $\begin{aligned} & 0-49 \\ & \mathrm{~mm} \end{aligned}$ | $\begin{gathered} 50-99 \\ \mathrm{~mm} \end{gathered}$ | $\begin{gathered} 100-149 \\ \mathrm{~mm} \end{gathered}$ | $\begin{gathered} \text { 150-199 } \\ \mathrm{mm} \end{gathered}$ | $\begin{gathered} \text { 200-249 } \\ \mathrm{mm} \end{gathered}$ | $\begin{gathered} \text { 250-299 } \\ \mathrm{mm} \end{gathered}$ | $\begin{gathered} \text { 300-349 } \\ \mathrm{mm} \end{gathered}$ | $\begin{gathered} \text { 350-399 } \\ \mathrm{mm} \end{gathered}$ | $\begin{gathered} 400-449 \\ \mathrm{~mm} \end{gathered}$ | $\begin{gathered} \text { 450-499 } \\ \mathrm{mm} \end{gathered}$ | $\begin{gathered} >500 \\ \mathrm{~mm} \end{gathered}$ |

### 3.4.1.2 O. mykiss population estimate

Table 3-10 shows the March 2010 O. mykiss population estimate for the lower Tuolumne River by length ( $<150 \mathrm{~mm}$ for YOY and juvenile; >150 mm for adults) and habitat type using the method of bounded counts (Hankin and Mohr 2001) for the study reach from RM 51.8 to RM 38.4 . Since the YOY/juvenile observations of $O$. mykiss were minimal ( $\mathrm{n}=1$ ), no population estimate for this lifestage was derived from the March 2010 survey. From an observed 13 adult $O$. mykiss in March 2010, an estimated population of 109 adults (with a $95 \%$ CI of $50-168$ ) was determined (Table 3-10). Adult $O$. mykiss were observed in all habitat types with the exception of "run body/tail" habitat.

Table 3-10. O. mykiss March 2010 bounded count population estimates between RM 51.8 and 38.4 by fish length and habitat type.

| Habitat | O. mykiss $<150 \mathrm{~mm}$ |  |  |  | O. mykiss $\geq 150 \mathrm{~mm}$ |  |  |  |

${ }^{1}$ Largest numbers seen in any single dive pass for each unit, summed over units. Note that because of the potential for the same fish to be assigned to different size classes on subsequent passes, summation of the largest numbers assigned to individual ( 50 mm ) size bins yields may overestimate total fish observed.
${ }^{2}$ Nominal confidence intervals calculated as +1.96 standard deviations.

### 3.4.1.3 Chinook salmon observations

Table 3-11 and Table 3-12 show the number of Chinook salmon observed within the study reach during the March 2010 surveys, based on the maximum count by pass, resulting in a total of 577 observations. All Chinook salmon were YOY and juveniles found within the 0-49 and 50-99 mm size classes. These salmon were seen in 16 different sampling units ranging from RM 51.6 to RM 38.8 (Table 3-11) and all habitat types (Table 3-12).

Table 3-11. Maximum counts of juvenile Chinook salmon by size class and sampling unit, March 2010.

No adult Chinook salmon were observed within the study reach. The complete Chinook salmon observation data by pass are shown in Appendix G.

### 3.4.1.4 Chinook salmon population estimate

Table 3-13 shows the March 2010 Chinook salmon population estimate for the lower Tuolumne River by length ( $<150 \mathrm{~mm}$ for YOY and juvenile; >150 mm for adults) and habitat type using the method of bounded counts (Hankin and Mohr 2001). Since there were no observations of adult Chinook salmon, no population estimate for this lifestage was derived from the March 2010 survey. From an observed 574 YOY/juvenile Chinook salmon in March 2010, an estimated population of 6,141 (with a $95 \%$ CI of 2,687-9,596) was determined (Table 3-10). Juvenile Chinook salmon were observed in all habitat types, with riffle habitat providing the highest number of observations and generating the largest portion of the population estimate (approx. 55\%).

Table 3-13. Chinook salmon March 2010 bounded count population estimates between RM 51.8 and 38.4 by fish length and habitat type.

| Habitat | Chinook salmon < 150 mm |  |  |  | Chinook salmon $\geq 150 \mathrm{~mm}$ |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Obs. ${ }^{1}$ | Est. ${ }^{2}$ | St. dev. | 95\% CI ${ }^{3}$ | Obs. ${ }^{1}$ | Est. ${ }^{2}$ | St. dev. | 95\% CI ${ }^{3}$ |
| Pool head | 48 | 67 | 22.2 | 48-111 | 0 | -- | -- | -- |
| Pool body/tail | 76 | 238 | 153.8 | 76-540 | 0 | -- | -- | -- |
| Riffle | 293 | 3,386 | 898.0 | 1,626-5,146 | 0 | -- | -- | -- |
| Run head | 11 | -- | -- | -- | 0 | -- | -- | -- |
| Run body/tail | 146 | 2,449 | 1,508.7 | 146-5,406 | 0 | -- | -- | -- |
| Total | 574 | 6,141 | 1,762.6 | 2,687-9,596 | 0 | -- | -- | -- |

${ }^{1}$ Largest numbers seen in any single dive pass for each unit, summed over units. Note that because of the potential for the same fish to be assigned to different size classes on subsequent passes, summation of the largest numbers assigned to individual ( 50 mm ) size bins yields may overestimate total fish observed.
${ }^{2}$ Estimate for run head habitat type for juvenile salmon not included in overall population estimate due to lack of multiple pass data to develop an expansion factor.
${ }^{3}$ Nominal confidence intervals calculated as +1.96 standard deviations.

### 3.4.1.5 Non-salmonid observations

Several other fish species were observed and counted during the March 2010 survey period (Table 3-14). Most other fish seen within the study reach were native species in the minnow (Cyprinidae) and sucker (Catostomidae) families. A combination of hardhead and Sacramento pikeminnow, along with Sacramento sucker accounted for $97.0 \%$. Other observed non-salmonid fish included catfish (Ictaluridae), centrarchids (largemouth bass, smallmouth bass), and sculpin (Cottidae), accounted for the remaining $3 \%$ of observations. Most centrarchids occurred toward the downstream end of the study reach where water temperatures were slightly warmer, while native suckers were found throughout the reach. The complete non-salmonid fish observation data are in Appendix G.

Table 3-14. Maximum counts of non-salmonid species by sampling unit, March 2010.

| RM | Sampling <br> unit | Habitat | CF | LMB | SMB | SC | HH/PM | SS |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

CF = catfish species; LMB = largemouth bass; SMB = smallmouth bass; $\mathrm{SC}=$ sculpin species; HH/PM = hardhead/Sacramento pikeminnow; SS = Sacramento sucker

### 3.4.2 August 2010

### 3.4.2.1 $\quad$ O. mykiss observations

During the August 2010 survey period, divers observed 682 O. mykiss ranging from $0-500 \mathrm{~mm}$ ( 50 mm size bins) based upon maximum counts of all dive passes in each sampling unit (Table $3-15$, Table 3-16). Approximately half of these fish (320) were YOY/juvenile ( $<150 \mathrm{~mm}$ ), with a total of 362 adults ( $>150 \mathrm{~mm}$ ) observed (Figure 5). Complete fish observation data by sampling unit and dive pass is presented in Appendix G.

The $O$. mykiss were observed in 22 different sampling units from RM 51.8 to RM 39.7 and in all habitat types (Table 3-15 and Table 3-16). Habitat use and reach-wide distribution of YOY/juvenile and adult $O$. mykiss were similar, based on the maximum count from dive passes (Figure 6a) highest in riffle and run body/tail habitats. Fish densities (Figure 6b) for juvenile size classes ( $<150 \mathrm{~mm}$ ) highest in riffle and pool head habitats. Juvenile size classes were also observed in each of the other habitat types, with lowest density in pool body habitats (Figure 6b). Adult-size classes (>150 mm) were observed in highest density in pool head habitats, with lower densities found in each of the other habitat types (Figure 6b).

Adult fish habitat use was concentrated at upstream sampling units (above RM 45.0) and primarily occurred at transitional run head and pool head habitats (Figure 7). Juvenile fish habitat use showed a similar distribution from upstream to downstream and occurred primarily at riffle habitat types, along with transitional run head and pool head habitat types (Figure 8).

Table 3-15. Maximum count of O. mykiss by sampling unit, August 2010 (data are divided into 50 mm total length size classes).

### 3.4.2.2 $\quad 0$. mykiss population estimate

Table 3-17 shows the August 2010 O. mykiss population estimate for the lower Tuolumne River by length ( $<150 \mathrm{~mm}$ for YOY and juvenile; >150 mm for adults) and habitat type using the method of bounded counts (Hankin and Mohr 2001). Out of an estimated 2,405 juveniles and 2,139 adults O. mykiss in August 2010 (an overall population estimate of 4,544), we estimated a $95 \%$ confidence interval of 625-4,185 and 727-3,552 for YOY/juvenile and adults, respectively (Table 3-17).

The relative differences between population estimates and observed fish counts are due to differences in habitat unit areas (e.g., run body/tail habitat types occupying approximately 20 times more habitat area than run head units (Table 3-2). This results in higher population estimates in some habitat types even though the observed counts may be similar or lower than those found in other habitat types. In August 2010, juvenile and adult population estimates were shown to be highest in run body/tail and riffle habitat types (Table 3-17).

Table 3-17. O. mykiss August 2010 bounded count population estimates by fish length and habitat type.

| Habitat | O. mykiss < 150 mm |  |  |  | O. mykiss $\geq 150 \mathrm{~mm}$ |  |  |  |

| Run body/tail | 134 | 1,432 | 886.2 | 134-3,169 | 116 | 1,215 | 677.3 | 116-2,542 |
| Total | 313 | 2,405 | 908.1 | 625-4,185 | 324 | 2,139 | 720.6 | 727-3,552 |

${ }^{1}$ Largest numbers seen in any single dive pass for each unit, summed over units. Note that because of the potential for the same fish to be assigned to different size classes on subsequent passes, summation of the largest numbers seen assigned to individual ( 50 mm ) size bins may overestimate total fish observed.
${ }^{2}$ Estimate for $O$. mykiss juveniles in pool head habitats not included in overall population estimate due to lack of multiple pass data to develop an expansion factor.
${ }^{3}$ Nominal confidence intervals calculated as +1.96 standard deviations. Standard deviation and confidence intervals undefined for multiple pass units with identical dive counts.

### 3.4.2.3 Chinook salmon observations

Divers observed a large number of juvenile Chinook salmon within the study reach during August 2010 as well as small numbers within the adult size classes ( $>150 \mathrm{~mm}$ ). Salmon were seen in 19 different sampling units from RM 51.8 to RM 31.9 (Table 3-18) and all habitat types (Table $3-19$ ). Most salmon were juveniles found within the $50-99 \mathrm{~mm}$ size class.

Table 3-18. Maximum counts of juvenile Chinook salmon by size class and sampling unit, August 2010.

Divers observed a total of seven adult Chinook salmon ( $>600 \mathrm{~mm}$ ) at two separate sampling units in the upper portion of the study reach at RM 51.8 and RM 50.3. A total of seven salmon in the 150-199 mm size class (a size class technically included as "adult", but not typically observed) were seen in three separate sampling units between RM 49.9 and 48.1. The complete Chinook salmon observation data by pass are shown in Appendix G.

### 3.4.2.4 Chinook salmon population estimate

Table 3-20 shows the August 2010 Chinook salmon population estimate for the lower Tuolumne River by length ( $<150 \mathrm{~mm}$ for YOY and juvenile; >150 mm for adults) and habitat type using the method of bounded counts (Hankin and Mohr 2001). Out of an estimated 6,338 juveniles and 117 adult Chinook salmon in August 2010 (an overall population estimate of 6,455), we estimated a $95 \%$ confidence interval of 3,291-9,385 and 14-249 for YOY/juvenile and adults, respectively (Table 3-20). The data show that the greatest estimated abundance of YOY and juvenile Chinook salmon occurred in run body/tail and riffle habitats, with the greatest estimated abundance of adults in the run body/tail habitat type (Table 3-20).

Table 3-20. Chinook salmon August 2010 bounded count population estimates by fish length and habitat type.

| Habitat | Chinook salmon < 150 mm |  |  |  | Chinook salmon $\geq 150 \mathrm{~mm}$ |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Obs. ${ }^{1}$ | Est. | St. dev. | 95\% CI ${ }^{2}$ | Obs. ${ }^{1}$ | Est. ${ }^{\text {a }}$ | St. dev. | 95\% CI ${ }^{3}$ |
| Pool head | 5 | 13 | 5.3 | 5-23 | 6 | 7 | 4.0 | 6-15 |
| Pool body/tail | 92 | 324 | 115.8 | 97-551 | 4 | 24 | 31.1 | 4-85 |
| Riffle | 400 | 2,149 | 571.2 | 1,029-3,268 | 0 | -- | -- | -- |
| Run head | 97 | 1,054 | 606.0 | 97-2,242 | 1 | 20 | 25.4 | 1-70 |
| Run body/tail | 379 | 2,798 | 1,307.6 | 379-5,361 | 3 | 65 | 53.8 | 3-170 |
| Total | 973 | 6,338 | 1,554.6 | 3,291-9,385 | 14 | 117 | 67.3 | 14-249 |

${ }^{1}$ Largest numbers seen in any single dive pass for each unit, summed over units. Note that because of the potential for the same fish to be assigned to different size classes on subsequent passes, summation of the largest numbers assigned to individual ( 50 mm ) size bins may overestimate total fish observed.
${ }^{2}$ Estimate adult salmon within riffle habitats for adult salmon not included in overall population estimate due to lack of multiple pass data to develop an expansion factor.
${ }^{3}$ Nominal confidence intervals calculated as $\pm 1.96$ standard deviations.

### 3.4.2.5 Non-salmonid observations

Several other fish species were observed during the August 2010 study period (Table 3-21). Most fish seen within the study reach were native species in the minnow (Cyprinidae) and sucker (Catostomidae) families. A combination of cyprinids (hardhead and Sacramento pikeminnow), along with Sacramento sucker accounted for $89.5 \%$ of observed non-salmonid fish. Non-native striped bass were observed in six sampling units (primarily pool body habitat) from RM 51.8 to RM 38.9. The complete non-salmonid fish observation data are in Appendix G.

Table 3-21. Maximum counts of non-salmonid species by sampling unit, August 2010.

## 4 DISCUSSION

### 4.1 Bounded Counts Study Assumptions

It should be noted that the bounded counts method was developed for use in smaller stream systems (Hankin and Mohr 2001) and applying the methodology to a larger system such as the Tuolumne River is only feasible provided key assumptions are satisfied. One critical assumption of the bounded counts approach is that all individuals have an equal probability of being observed. As noted above, this assumption may be challenged in locations with large numbers of juvenile Chinook salmon, due to low visibility conditions in deeper pool habitats, as well as low visibility due to light and background turbidity variations within the river between seasons or
from upstream to downstream. For these reasons, the resulting population estimates may be lowbiased.

A second assumption of the bounded counts method is that observation efficiency is not $100 \%$, so the number of fish seen in any single dive pass is, in general, an underestimate of the true number of fish present. For a closed population where fish do not migrate into or out of the unit between dives, the maximum number of fish seen over multiple passes is a low-biased estimator of the true population. However, because larger habitat units were subsampled at some locations, for run habitat types in particular, the resulting density expansions may have introduced a high-biased estimate of the true population size since fish are able to migrate freely into and out of the searched area due to the lack of habitat boundaries relevant to the sampled fish (e.g., riffle transitions) in many locations.

### 4.2 Variations in O. mykiss Population Estimates

### 4.2.1 March Survey Period

Overall, the March 2010 population estimate of 109 adult $O$. mykiss ( $>150 \mathrm{~mm}$ ) was low, with virtually no representation of juvenile size classes ( $<150 \mathrm{~mm}$ ) relative to adults (Table 3-10). Although the high numbers of Chinook salmon juveniles observed during the March 2010 surveys (Table 3-12) may have resulted in misidentification of some $O$. mykiss within the same area, the low numbers of juvenile $O$. mykiss observed is consistent with a winter-spring spawning period that begins in February (Moyle 2002). The low number of adult O. mykiss observed are consistent with the results of the March 2009 survey. The low numbers of O. mykiss during spring were attributed to one or more of the following potential causes:

1. Adult $O$. mykiss have a heterogeneous (i.e., "patchy") distribution and it appears that even though the 2010 winter sampling efforts were conducted in the same reach as summer surveys, upstream of Roberts Ferry Bridge (RM 39.5), the resulting observation of adults remains low. Information from other sources (e.g., from angling or tracking) may identify whether habitat use is distributed farther downstream.
2. Adult $O$. mykiss may be more furtive in winter, swimming into or occupying deeper portions of pools or out of range of the diver visibility, which is also reduced in winter due to lower light levels and increased turbidity. Nighttime dive surveys could be considered in future surveys, since low light situations tend to reduce the startle reflex of O. mykiss.
3. Lastly, adult $O$. mykiss may be altogether absent from the survey reach because they have migrated downstream of RM 29 or did not survive the previous over-summer conditions. This could be confirmed by any of: a) catch and release angling outside of the survey reach, b) capture, implantation of acoustic tags and tracking as provided in the TID/MID (2007) study plan, or c) video observations at the Districts Alaska type counting weir recently deployed at RM 24 in September 2009.

### 4.2.2 August Survey Period

The August 2010 population estimate of 4,544 O. mykiss indicates a relatively equal proportion of juveniles $(2,405)$ relative to adults $(2,139)$ (Table 3-17). In comparison to the July 2008 results of 2,472 juveniles and 643 adults, and the July 2009 results of 3,475 juveniles and 963 adults, the August 2010 results indicate a relatively similar number of juveniles over the 2008-2010 summer
sampling periods, and a noticeable increase in the number and proportion of adults. Juvenile $O$. mykiss population estimates would be expected to vary from year-to-year due to the large number of potential eggs deposited by each additional female spawner. Also, the juvenile estimates (Table 3-17) are all within the with 95\% CIs computed from 2008-2010 (Stillwater Sciences 2008b, 2010).

In addition any upstream migration of O. mykiss, the August 2010 adult O. mykiss population estimate may relate to conditions in the river below La Grange dam that were greatly influenced by flood control releases occurring from April thru July 2010. These releases extend cooler water temperatures farther downstream. These releases resulted in flows that spilled over the La Grange dam and may have resulted in the introduction of $O$. mykiss into the river from upstream reservoirs. In August 2010, small groups of larger sized ( $>250 \mathrm{~mm}$ ) adult O. mykiss were observed in run body and pool body habitats downstream of where they were observed in previous survey years (2008 and 2009). These adults appeared as similar in size, coloration, and condition and were observed schooling together in circular patterns. Larger numbers of smaller sized (150-200 mm) adult fish were also observed in August 2010 (Figure 5). These sized fish would not have been able to come from the 2010 year class. This suggests the origin of the larger number of smaller sized fish may be due to upstream flood control releases. The larger sized fish ( $>250 \mathrm{~mm}$ ) may have arrived from upstream, or by migration from downstream locations in the Tuolumne River or San Joaquin Basin.

### 4.3 O. mykiss Distribution in Relation to Water Temperature

### 4.3.1 March 2010

During the March 2010 snorkel surveys, water temperatures remained below $14.5^{\circ} \mathrm{C}$ throughout the study reach, with daily average temperatures exceeding $13.0^{\circ} \mathrm{C}$ only at the lowest sampling unit (RM 38.4) on 7 March 2010. These temperature conditions are not thought to particularly affect the distribution of $O$. mykiss and it is likely that some other factor may also explain the decreasing O. mykiss density with distance downstream of La Grange Dam . All O. mykiss observed were found at or upstream of RM 38.5, similar to the March 2009 survey. As discussed above in Section 4.2, presence/absence of $O$. mykiss downstream of the study reach could be confirmed by any of: a) catch and release angling outside of the survey reach, b) capture, implantation of acoustic tags and tracking as provided in the TID/MID (2007) study plan, or c) video observations at the Districts Alaska type counting weir deployed at RM 24 in September 2009. Counting weir results show only one adult O. mykiss ( 276 mm ) detected during the operational period from September 22, 2009 through January 31, 2010 (TID/MID 2010). Preliminary results from an acoustic tag and tracking studying initiated by the Districts' in February 2010 are currently not available, pending completion of the study.

### 4.3.2 August 2010

To test Hypothesis \#1 that summertime distribution of observed life stages of O. mykiss across suitable habitat is related to ambient river water temperature, we compared water temperature data taken from thermographs to fish density in the sampled units. The data show that temperatures increase in the downstream direction (Section 3.3.2, Table 3-6) and that the density of adult $O$. mykiss ( $>150 \mathrm{~mm}$ ) generally decreased along this same gradient (Figure 9). In sampling units where fish were seen, density of adult fish was generally similar from just downstream of La Grange Dam to approximately RM 47, with a peak density near RM 45 (Figure
9). The density of adults then decreased markedly in the downstream direction. As noted in Section 4.2.2, conditions in the river below La Grange dam were greatly influenced by flood control releases that extend cooler water temperatures farther downstream.

Similar to adults, the density of YOY and juvenile O. mykiss decrease in the downstream direction, with generally similar distribution from just downstream of La Grange Dam to approximately RM 43 (Figure 9). Peak density of juveniles occurred near RM 45, with very low densities below RM 43. Juveniles were found in six out of seven riffle sampling units, indicating a strong preference for this habitat type. However, juveniles were also observed in five out of six sampling units, although in lower density (Table 6a and Table 6b). Generally, juveniles were not expected in this habitat type at downstream locations for a number of reasons, including predation and territorial exclusion by the larger size classes of $O$. mykiss. The occurrence of juveniles in this habitat type may also have been related to the earlier flood control releases, where juveniles were simply displaced from an upstream habitat due to increased water velocity, or where physical habitat (e.g. depth, velocity, cover, food supply) became available as microhabitat along the stream margin of run habitats.

### 4.4 Habitat Associations of O. mykiss and Chinook salmon Observations

### 4.4.1 March 2010

Table 4-1 and Table 4-2 show the range of cover and substrate components observed during habitat mapping for each habitat type where O. mykiss and Chinook salmon were present during the March 2010 surveys. Variations in cover types and amounts were limited in all sampling units, with higher percentages of the "No Cover" class found throughout the reach (Appendix D2). For this reason, the cover results do not provide a meaningful basis for establishing a relationship with habitat use by juveniles or adults of either species. Chinook salmon juveniles were the most observed salmonid during the surveys and were observed primarily in riffle and transitional pool head and run head habitats where higher percentages of cobble were reported (Table 4-1).

Table 4-1. Cover and substrate type found in sampling units with 0 . mykiss present during the March 2010 snorkel surveys.

| Cover type | Pool body/tail | Pool head | Riffle | Run body/tail | Run head |

### 4.4.2 August 2010

Table 4-3 and Table 4-4 show the range of cover and substrate components observed during habitat mapping for each habitat type where $O$. mykiss and Chinook salmon were present during the August 2010 surveys. As in March 2010, variations of cover types and amounts were limited in all sampling units, with higher percentages of sampling units with no cover found throughout the reach (Appendix D-2). Therefore cover results do not provide a meaningful basis for establishing a relationship with habitat use by juveniles or adults of either species. Nevertheless, O. mykiss and Chinook salmon were observed primarily in riffle and run body/tail habitats where higher percentages of cobble were reported relative to other substrates associated with those habitat types (Table 4-3).

Table 4-3. Cover and substrate type found in sampling units with 0 . mykiss present during the August 2010 snorkel surveys.

### 4.5 Habitat Use at Restored and Reference Sites by 0. mykiss and Chinook salmon

Hypothesis \#2 states that the density of $O$. mykiss juveniles and adults is the same in restored sites as in nearby reference sites in the Tuolumne River. This hypothesis was originally formulated with the intention of testing habitat use at planned gravel augmentation sites (TID/MID 2007). However, other than the CDFG gravel addition projects near Old La Grange Bridge, completed from 2001-2003, and the joint Tuolumne River Technical Advisory Committee/Friends of the Tuolumne (FOT) gravel augmentation at Bobcat Flat (RM 43) in 2005, no further gravel augmentation projects have been implemented since that time. This has limited the sampling replication and statistical power to detect any differences between restored and reference sites.

As a means to evaluate habitat use of these restoration sites, observed densities of $O$. mykiss juveniles and adults were compared at the three habitat types that were sampled within the restoration sites to the same habitat types surveyed elsewhere in August 2010. The low number of O. mykiss observations in March 2010 do not allow for meaningful comparisons. Figure 10 shows the $O$. mykiss density of juveniles and adults at pool head, riffle, and run head habitats types sampled in August 2010 from sampling units found at both the restoration sites and from all similar sample units within the study reaches upstream of RM 38.0. For juvenile $O$. mykiss the densities show a relatively high use of riffle habitat at restoration sites when compared with other riffle sampling units; with relatively similar use of run head habitat at the upstream restoration sites; and an overall low density in pool head habitats found at the downstream portion of the reach (Figure 10). These same patterns appear for adult O. mykiss the densities throughout the reach.

A similar evaluation was done using juvenile Chinook salmon. Figures 11 and 12 show juvenile Chinook densities as sampled in March 2010 and August 2010, respectively for the same three habitat types. In March 2010, juvenile Chinook densities at the restoration sites were greater in each of the habitat types when compared to the reference sampling units (Figure 11), with the exception of riffle habitats between RM 44-46. In August 2010, juvenile Chinook densities either exceeded or were similar to the reference units (Figure 12). Considering the similar habitat preferences for juvenile O. mykiss and juvenile Chinook salmon, it appears that salmonid use of restoration sites is similar, or possibly enhanced within riffle habitats, when compared with nearby reference sites. Additional replication through either an increased number of gravel augmentation sites, or an increased number of survey events would be needed to improve the statistical power enough to detect whether significant differences in habitat use exist.

### 4.6 Comparison to August 2010 Reference Count Snorkel Surveys

Results from the August 2010 snorkel data were compared to observations made during the August 2010 reference count snorkel survey (Kirihara 2010) for the sampled reach common to both surveys and within sampling units surveyed during both sampling events (Table 4-5 and Table 4-6). The August 2010 BCE data are observations from the first pass of the multiple pass bounded count estimation method to allow a direct comparison to August 2010 reference survey, which came from single pass snorkel surveys that employ catch-per-unit-effort (CPUE) methodology. Note that the reference count surveys were not conducted in March, precluding comparison with the March 2010 surveys.

Table 4-5. Salmonid observations in August reference count (single pass) and August BCE (first pass) surveys in 2010 within the reach sampled during both studies.

| August 2010 reference count snorkel survey |  |  |  |  | August 2010 BCE snorkel survey |  |  |  |  |

### 4.6.1 $\quad$ O. mykiss observations

A total of 195 O. mykiss juveniles and 73 adults were observed in August 2010 reference count survey, while 210 juveniles and 253 adults were observed in the August 2010 BCE survey (Table $4-5)$. The between-site comparison shows similar longitudinal trends for juveniles, with observations and density generally decreasing in the downstream direction (Table 4-6). In both surveys, the greatest abundance of $O$. mykiss juveniles occurred within riffle habitat near RM 50.6 (Table 4-6). Adult $O$. mykiss abundance was lower for the August reference survey when compared with the August BCE survey at shared sampling sites. This was particularly evident at the upstream riffle location near RM 50.6 where no adults were observed during the reference survey and 34 adults were observed during the BCE survey (Table 4-6).

It should be noted that the August 2010 reference count survey data were collected from sites established in past years and targeted based on prior years' data as likely areas of relatively high O. mykiss abundance. The area surveyed during the August BCE surveys was greater (by an order of magnitude in most cases) than in June (Table 4-6). The reference count snorkel survey reoccupies the same sampling units and areas on an annual basis, produces a yearly index with which to evaluate yearly trends, assuming reoccupied sampling units and areas are representative of the entire reach. The BCE methodology (Hankin and Mohr 2001) produces a population estimate, with appropriate confidence intervals, that, due to the incorporation of multiple passes in each unit and greater area searched in each unit and along the reach, can be used to evaluate habitat- and reach-wide distribution patterns.

### 4.6.2 Chinook salmon observations

A total of 142 Chinook salmon juveniles were observed during the August 2010 reference survey, while a total of 889 juveniles were observed during the August BCE survey (Table 4-5). As noted above, the total area in the BCE surveys is greater than in the reference surveys. Salmon were observed in each habitat type sampled by the two methods. Although a stream-type life history strategy is not believed to be common for Chinook salmon in the Tuolumne River, the presence of juveniles in mid-summer indicates that conditions (e.g., water temperature, food availability) in summer 2010 were suitable for survival in upper portions of the reach.

## 1 BACKGROUND AND PURPOSE

Fisheries monitoring for the Don Pedro Project (FERC Project No. 2299) by the Turlock Irrigation District (TID) and Modesto Irrigation District (MID) has long documented the presence of Oncorhynchus mykiss (O. mykiss) in the lower Tuolumne River (TID/MID 2005). On March 19, 1998 the National Marine Fisheries Service (NMFS) first listed the Central Valley steelhead as threatened under the Endangered Species Act (ESA). After several court challenges, NMFS issued a new final rule relisting the Central Valley steelhead on January 5, 2006 ( 71 FR 834). In a separate process regarding terms of the 1996 FERC license amendments for the Project, NMFS staff provided input to a draft limiting factors analysis for Tuolumne River salmonids (Mesick et al 2007) and included recommendations for developing abundance estimates, habitat use surveys and anadromy determination of resident $O$. mykiss. These recommendations were conceptually used to develop the Districts FERC Study Plan (TID/MID 2007) which was the subject of an April 3, 2008 FERC Order. As part of the Order, the Districts are required to conduct population estimate surveys in summer (June/July) and winter (February/March), starting in summer 2008 to determine O. mykiss population abundance by habitat type.

The purpose of the proposed $O$. mykiss population surveys is to provide population size estimates over several sampling seasons of differing environmental conditions to determine habitat use and needs within the lower Tuolumne River. The surveys will be used to examine the following hypotheses:

Hypothesis 1: Summertime distribution of suitable habitat by observed life stages of $O$. mykiss is related to ambient river water temperature.

Hypothesis 2: Habitat use by O. mykiss juveniles and adults observed in the Tuolumne River occurs at the same density in both restored and nearby reference sites.

As recommended by Stillwater Sciences (Stillwater), the surveys will employ a two-phase sampling approach of potential $O$. mykiss habitat using snorkel surveys for the development of a "bounded count" population estimate (Hankin and Mohr 2001). Although the methodology presented below discusses both repeated dive counts and calibration by depletion electrofishing, current ESA permit restrictions for both NMFS Section 10(a)(1)(A) permit No's 1280 (TID) and 1282 (Stillwater) do not allow sufficient incidental take to conduct the second phase surveys at this time using electrofishing. Discussions with NMFS permitting staff and Stillwater have occurred since submittal of the 2007 FERC Study Plan, resulting in a pending formal request to NMFS by Stillwater for modification of Permit 1282 (see Section 6 below). The Section 10 Permit 1280 issued to TID in 2005 authorized only up to 5 juvenile $O$. mykiss annually by electrofishing that was further restricted to River Mile $25-30$ during September to November. Thus that permit is not applicable or adequate to the season, location, and fish numbers needed to conduct the electrofishing for this population estimate study. Consequently, the July 2008 survey was conducted using snorkel surveys only as provided for in the 2007 study plan. It is not anticipated that the pending permit amendment request will be resolved prior to the winter 2009 survey, as such this will be conducted using snorkel surveys. If the pending amendment request is resolved prior to July 2008, then summer 2009 surveys will be conducted using the combined method presented below.

## 2 FIELD SAMPLING AND DATA COLLECTION

The two-phase stratified sampling design involves snorkeling pre-selected habitat units (e.g., riffle, run, pool, etc.) multiple times in order to quantify the variance associated with density and
subsequent population estimates. Habitat units are selected using stratified random sampling where the habitat types possess a pre-determined probability of occurrence within areas where $O$. mykiss have been frequently observed during the summer in the lower Tuolumne River, extending from approximately river mile (RM) 52-40 during summers and potentially extending to near the city of Waterford (RM 30) during colder winter conditions.

In a typical Phase 1 sampling approach, primary snorkel surveys (Edmundson et al. 1968, Hankin and Reeves 1998, McCain 1992, Dolloff et al. 1996) will be conducted across a subset of all habitat units. In Phase 2, approximately $20-70 \%$ of each habitat type sampled will be randomly selected for replicated surveys by either repeated dive counts or depletion electrofishing (Reynolds 1996).
Although the bounded counts methodology was developed for use in smaller stream systems (Hankin and Mohr 2001), applying the methodology to a larger system such as the Tuolumne River is feasible provided key assumptions are satisfied. A critical assumption of the bounded counts approach is that all individuals have a chance of being observed. This may not be practically attainable due to the depths of some of the in-channel mining pits and also potentially due to low visibility conditions occurring at downstream locations or due to winter-time sediment inputs during rain events. Hankin and Mohr (2001) found that their survey designs were suitable for coho salmon (O. kisutch), but they were less confident about applying the methodology to $O$. mykiss juveniles because the fish's furtive nature may violate the assumption that all fish have an observation probability $>0$. Sampling sites and methods may be modified following initial surveys because local conditions cannot be anticipated and may dictate the use of other schedules, locations, or techniques. Stillwater Sciences will notify TID, FERC, and permitting authorities if substantive changes in the study design, methods or schedule are anticipated.

### 2.1 Habitat Typing

On-the-ground mapping of potential habitat for $O$. mykiss will be delineated on digital ortho-rectified aerial photographs and information from previous habitat mapping efforts. Appendices A and B shows preliminary habitat units from RM 52-30 based upon habitat mapping conducted by Stillwater Sciences (2008) between La Grange Dam (RM 52) and Roberts Ferry Bridge (RM 40) (Appendix A) as well as preliminary habitat units from RM 40 to Waterford (RM 30) based upon mapping conducted by McBain \& Trush (2004) and EA Engineering (1997) shown in Appendix B. The Appendix B habitat maps will be updated for flow and morphological characteristics in the field in late February and late June in each year. The final habitat maps will delineate all potential $O$. mykiss habitats according to the major types listed in Table 1, as well as transitional habitats that may be preferentially used by various size classes (i.e., pool heads, pool bodies, pool tails, run heads, run bodies, run tails, and riffles).

Table 1. Coarse scale habitat types to be used during snorkel surveys
$\left.\begin{array}{c|c|c}\hline \begin{array}{c}\text { Habitat } \\ \text { Type }\end{array} & \text { Description }^{\text {a }} & \begin{array}{c}\text { Approximate } \\ \text { Depth }\end{array} \\ \hline \text { Riffle } & \begin{array}{c}\text { Shallow with swift flowing, turbulent water. Partially exposed substrate } \\ \text { dominated by cobble or boulder. Gradient moderate (less than 4\%). }\end{array} & 0-4 \mathrm{ft} \\ \hline \text { Run } & \begin{array}{c}\text { Fairly smooth water surface, low gradient, and few flow obstructions. } \\ \text { Mean column velocity generally greater than one foot per second (fts }{ }^{-1} \text { ). }\end{array} & 4-10 \mathrm{ft} \\ \hline \text { Pool } & \text { Slow flowing, tranquil water with mean column water velocity less than } 1 \\ \mathrm{fts}^{-1} .\end{array}\right]>10 \mathrm{ft}$.

[^8]A Geographic Information System (GIS) will be used to update and refine habitat maps prior to thorough field verification of flow, depth, and habitat conditions in the river. Within each reach, individual habitat units will be digitized as two-dimensional features of varying shapes, or polygons, where each unit is a discrete functional habitat, as defined above. This approach is consistent with the general techniques of McCain (1992), Thomas and Bovee (1993), and Cannon and Kennedy (2003) and allows a flexible approach to evaluating habitat and habitat use patterns at a scale that can be easily delineated given available data, readily depicted, and is ecologically meaningful for aquatic species.

Habitat units will be assigned a natural sequence order (NSO), starting at one which is the first unit at the upstream end of the site, and a habitat type unit number ( $1 \ldots \mathrm{~N}$ pools, runs and riffles). The maximum depth, length and width (usually at $1 / 3$ and $2 / 3$ of the units length) will be recorded and flagging tied at both upstream and downstream ends of units to be surveyed. Pertinent information such as date, unit number, and type is included on the flag. Lastly, the upper and lower end of each unit will be located by GPS and mapping from previous efforts will be verified or updated.

### 2.2 Sample Site Selection

After all potential habitat units are typed and all pertinent information recorded, a subset of each habitat unit type will be selected for single-pass snorkel surveys. Although additional units may be selected at gravel augmentation and other in-channel restoration sites (See Hypothesis 2), selection for sampling proceeds by random selection of the starting sampling unit in the upper survey section, followed by a systematic uniform sampling of the remaining units in the survey reach. For example, every $3^{\text {rd }}, 4^{\text {th }}$ or larger selection interval will be used to distribute the selected units uniformly across the survey reach.

Because the total length of river sampled affects the confidence bounds of the resulting $O$. mykiss population estimates, at least $10 \%$ of the total length of a given habitat type and a minimum of 5 units of each type will be sampled. Based upon preliminary habitat mapping and median unit lengths of various habitat types, Table 2 shows that 63 sampling units for the winter surveys will be selected from representative locations between RM 52-30 to meet the minimums above. This estimate further assumes that, since detailed habitat type mapping has not been conducted from RM 40-30, habitat type distribution and median length from RM 40-30 are similar to RM 52-40, as determined by summer 2008 habitat type mapping (Stillwater Sciences 2008). The exact number sampled will be determined after random selection of the habitat units prior to study implementation.

During summer, an estimated 35 units will be selected for single-pass snorkel survey from representative locations between RM 52-40 (Table 2). For both winter and summer surveys, the number and location of habitat units may be adjusted if initial systematic sampling does not allow the study to adequately to test Hypothesis 2.

Table 2. Estimated number of sampling units that will meet study design assumption of sampling at least $10 \%$ of the total length of a given habitat type.

 length to determine a minimum number of units
${ }^{\mathrm{e}}$ Actual river length from RM 40-30

### 2.3 Sampling Period

Winter sampling will begin in late February with systematic random selection of habitat units from RM 52-30, based upon summer 2008 maps (Appendix A) and previous habitat typing between RM 40-30 (Appendix B). Following habitat selection, Stillwater will use single-pass snorkel surveys and second phase calibration surveys within units of each type to develop uncertainty and bias estimates. Second phase sampling will be conducted using multi-pass snorkel surveys and/or depletion electrofishing methods as allowed under applicable permits (See Section 6).

Summer sampling will use habitat maps from RM 52-40 developed in summer 2008 (Appendix A). Although no additional habitat mapping is anticipated following winter 2009 surveys, habitat unit flagging will be established in advance of each snorkel survey effort and seasonal changes in habitat distribution may force revision of habitat type maps, specifically the upper and lower boundaries of habitat units and/or channel margins, prior to summer 2009 surveys.

### 2.4 Measurement Parameters and Sampling Methods

Multiple parameters will be measured in order to meet the objectives for this study (Table 3). Photos and GPS locations will be taken at each site, and site locations identified on GIS maps corresponding to mapped aquatic habitat units. General site information recorded at fish sampling locations will include site name, GPS coordinates, time, date, and crew member names. In situ water quality parameters (Temperature, dissolved oxygen, and conductivity) will be collected using a precalibrated multi-probe (YSI 85, Yellow Springs Instruments, Yellow Springs, OH). Underwater visibility will also be estimated into the sun and away from the sun using a Secchi disk to monitor any changes in visibility. Dissolved oxygen probes will be recalibrated at each site and checked for accuracy against concentrations measured in Winkler titrations (Grasshoff et al 1983) at the beginning and end of the sampling effort using a dissolved oxygen test kit.

Table 3. Measurement parameters and methods for snorkel surveys

| Parameter | Method | Metric/Descriptor | Method <br> Reporting <br> Limit |  |
| :---: | :---: | :---: | :---: | :---: |

### 2.4.1 Snorkel Surveys

Snorkel surveys will be conducted during daylight hours (7:00am-5:00pm winter; 6:00am-8:00pm summer). A two phase survey design will be used to survey the seven different strata (Table 4). At the first phase, single-pass dive surveys will be conducted by a four to five person crew depending upon river flows and underwater visibility. Sampling units will generally be sampled from downstream to upstream in dive lanes using a zigzag pattern, passing fish and allowing them to escape downstream of the diver. If fish are observed to escape upstream, the diver will take care to avoid counting these fish twice. Divers will record their observations of pertinent attributes (Table 3) and numbers of $O$. mykiss and Chinook salmon ( $O$. tshawtscha) observed; with fish lengths to be estimated in 50 mm size ranges using a scale model or markings on the slates to correct for underwater size distortion. After the first dive pass is completed a tab is then pulled to determine if the unit is included in the second phase of sampling.

Table 4. Preliminary sample unit selection and survey count.

| Run head | 9 | 1 | 2 | 2 | 5 | 1 | 2 | 2 |  |  |  |  |  |  |  |  |
| Run body | 9 | 1 | 2 | 2 | 5 | 1 | 2 | 2 |  |  |  |  |  |  |  |  |
| Run tail | 9 | 1 | 2 | 2 | 5 | 1 | 2 | 2 |  |  |  |  |  |  |  |  |
| Total |  |  |  |  |  |  |  |  |  | 63 | Total | 28 | Total | 35 | Total | 28 |

The second phase of sampling collects data that will later be used to extrapolate dive counts to total population estimates by three passes of either repeated dive counts or depletion electrofishing. Ideally, if the count of $O$. mykiss from the Phase 1 snorkel survey is less than or equal to 20 individuals then three additional dive passes are made. If electrofishing is permitted, all units with a count of juvenile $O$. mykiss counts greater than 20 individuals will be surveyed by electrofishing. Lastly, occurrence of other native and non-native fish species will be recorded as presence/absence.

### 2.4.2 Electrofishing at Riverine Sites

If employed during the summer 2009 survey, electrofishing will be conducted by a 4 person crew during the daylight hours (6:00am-8pm) following the dive surveys. Ideally, 3-pass electrofishing will be used on all second phase dive units where the first dive pass exceeded 20 O. mykiss. Dive units that require electrofishing for dive calibration will be completed as soon as possible after the dive survey.

Shallow water habitat may be sampled using back pack electrofishing units while deep water habitat may be sampled using a boat electrofishing unit. Back pack electrofishing in shallow waters less than 3-4 ft depth will be conducted using two or more Smith-Root back pack electrofishers (Model LR-24 or Model 12 with 11 -inch anode rings and standard "rat-tail" cathodes). Boat electrofishing may be used in deeper riverine habitats using a boat mounted Smith Root 1.5 KVA electrofishing unit. To ensure the health of all fish captured during electrofishing, all electrofishing will be conducted in accordance with NMFS (2000) electrofishing guidelines and an electrofishing logbook will be maintained and updated at each sampling site.

Depending upon river flows and depth, electrofishing will use block nets placed at the upstream and downstream ends of the unit to be fished, taking care to avoid disturbance of the unit during net setup. Block nets will be set up where possible to prevent fish from moving out of the unit. If block nets are not feasible, then a snorkeler may be stationed at the upstream end of a unit to observe any fish moving out of the unit.

First pass electrofishing will proceed slowly and deliberately upstream from the downstream end of the unit; members of an electrofishing crew will move to the top and back down to the bottom working closely together. To maintain equal effort on subsequent passes, electrofishing time (seconds) will be recorded to allow for any adjustments in sampling effort. A fourth pass will be conducted if one of the following applies:

1. The number of $O$. mykiss caught on the $2^{\text {nd }}$ pass exceeds the number of $O$. mykiss caught on the $1^{\text {st }}$ pass.
2. The number of $O$. mykiss caught on the $3^{\text {rd }}$ pass is greater than or equal to 25 percent of number caught on the $2^{\text {nd }}$ pass.

The procedure may be modified in riffle habitats to facilitate capture of shocked fish in fast water. In the riffle strata, a pass consists of a sweep from the top to the bottom of the unit. Depending on the water velocity, block nets may or may not be set at the upstream end of riffle units.

### 2.4.3 Fish Handling Protocols

Any fish captured during electrofishing surveys will be processed, and information collected regarding species identification, fork length (FL, mm), weight (g), and, if applicable, notes on general condition. All fish will be rapidly retrieved using dip nets and placed immediately into aerated live wells or buckets with water. Large fish will be kept separate from juvenile fish to avoid confinement predation. Fish will be identified to species and origin (hatchery or wild stock) where possible. Fish that are weighed and measured will be anesthetized using clove oil to minimize handling stress. After all fish are identified, counted, and measured, fish will be held for approximately 10 minutes, until they show signs of "normal" swimming patterns and behavior.

### 2.5 Hypothesis Testing

The purpose of the proposed $O$. mykiss population surveys is to provide population size estimates over several sampling seasons of differing environmental conditions to determine habitat use and needs within the lower Tuolumne River. The surveys will be used to examine the following hypotheses:

Hypothesis 1: Summertime distribution of suitable habitat by observed life stages of $O$. mykiss is related to ambient river water temperature.

Hypothesis 2: Habitat use by O. mykiss juveniles and adults observed in the Tuolumne River occurs at the same density in both restored and nearby reference sites.

While the selection for sampling proceeds by random selection of the starting sampling unit in the upper survey section, followed by a systematic uniform sampling of the remaining units in the survey reach, additional units adjacent to or near restoration sites may be non-randomly selected to provide treatment and control locations to test Hypothesis 2, especially during winter 2009 surveys when low ambient river water temperatures obviate the need to test Hypothesis 1.

### 2.6 Field Work Notification

To ensure field staff safety and to satisfy scientific collecting permit requirements, the parties listed in Table 5 will be notified in advance of the proposed sampling in as required to confirm sampling dates.

Table 5. Field Work Notification

Prior to mobilization, planned river operations by the Districts will be checked to determine if fish sampling would be safe under the anticipated flow and all parties will be notified of any delay or modification to the sampling schedule.

## 3 QUALITY ASSURANCE

The objective of data collection for this Project is to produce data that represent as closely as possible, in situ conditions of the Tuolumne River with respect to river flow conditions, water quality, abundance and habitat use by $O$. mykiss. To meet this objective, field sampling, sample preparation, and analysis will follow general guidelines outlined in USEPA (2002) by ensuring that:

- the project's objectives, hypotheses and data quality objectives are identified and agreed upon,
- the intended measurements and methods are consistent with project objectives,
- the assessment procedures are sufficient for determining if data of the type and quality needed and expected are obtained, and
- any potential limitations on the use of the data can be identified and documented.

Aquatic environments are inherently variable, but management decisions must be based on a data from a limited number of locations and often collected in short time periods. How well the information collected represent the reach or river-wide fish population depends upon a systematic approach to quality assurance.

### 3.1 Data Quality Objectives for Measurement Data

The data quality parameters used to assess the acceptability of the data are precision, accuracy, representativeness, comparability, and completeness. Precision measures the reproducibility of measurements under a given set of conditions. Analytical precision is limited to water quality and physical habitat characteristics (Table 6). Accuracy is an expression of the degree to which a measured or computed value represents the true value. Field accuracy is controlled by adherence to sample collection procedures.

Table 6. Data quality objectives for field parameters

| Parameter | Units | Accuracy | Precision | Completeness |
| :--- | :---: | :---: | :---: | :---: |
| Dissolved Oxygen | $\mathrm{mg} / \mathrm{L}$ | $\pm 0.5$ | $10 \%$ | $90 \%$ |
| Temperature | ${ }^{\circ} \mathrm{C}$ | $\pm 0.5$ | $5 \%$ | $90 \%$ |
| Conductivity | umhos/cm | $\pm 5 \%$ | $\pm 5 \%$ | $90 \%$ |
| Depth | meters | $\pm 0.2$ | $\mathrm{~N} / \mathrm{A}$ | $\mathrm{N} / \mathrm{A}$ |
| Visibility (Secchi) | meters | $\pm 0.05$ | $\mathrm{~N} / \mathrm{A}$ | N/A |

- Representativeness expresses the degree to which data accurately and precisely represent an environmental condition. For this study, monitoring site selection will be conducted based on physical habitat attributes. Additionally, specific measurement parameters have been identified as relevant based on numerous studies indicating factors associated with species distribution.
- Comparability expresses the confidence with which one data set can be evaluated in relation to another data set. For this biological assessment, comparability of data will be established through the use of standard analytical methodologies and reporting formats.
- The project goal for completeness, a measure of the amount of data that is determined to be valid in proportion to the amount of data collected, will be $90 \%$ for analytical water quality parameters. The data quality objective for completeness for all components of this study is 90\%.

### 3.2 Training Requirements/Certification

Specialized training is required for the proposed sampling activities, however none of the sampling activities require outside certification from an agency or another entity. Required permits for biological sampling are discussed in Section 5 . Field crews will be staffed by a variety of qualified personnel, which due to the nature of extended field activities, will necessarily be rotated in and out of the field.

### 3.3 Instrument/Equipment Testing, Inspection, and Maintenance Requirements

To ensure proper equipment performance in the field, maintenance and operational procedures, including preventative maintenance, will be performed on all YSI multiprobes (temperature, dissolved oxygen, and conductivity). YSI maintenance will be recorded in a logbook with the date the maintenance was performed and the initials of the technician. When the instruments are not deployed, the calibration or storage cup will be used to protect sensors from damage and desiccation.

### 3.4 Instrument Calibration and Frequency

Field probes used for field sampling will be calibrated prior to use, midway through each sampling event, and at the end of each sampling event. Measurement devices for conductivity will be checked against a standard whose source is different than that selected for calibration. Dissolved oxygen will be checked against aerated water whose oxygen content is established by the Winkler method (Grashoff et al 1983). Temperature does not require calibration because of the unvarying nature of the temperature sensor and its conditioning circuitry.

### 3.5 Reconciliation with Data Quality Objectives

If data do not meet the project's specifications, the following actions will be taken. First, the task leaders working with the field crew leaders (in some cases they will be the same person) will review the errors and determine if the problem is equipment failure, calibration/maintenance techniques, or monitoring/sampling techniques. They will suggest corrective action. If the problem cannot be corrected by training, revision of techniques, or replacement of supplies/equipment, then the task leaders will review the data quality objectives (DQOs) and determine if the DQOs are feasible. If the
specific DQOs are not achievable, they will determine whether the specific DQO can be relaxed, or if the parameter should be eliminated from the monitoring program.

### 3.6 Data Management

All field data will be amassed in a quality-checked database and summarized. QA checks will be applied to all data before data entry and data will be stored on Stillwater Sciences servers. Full backup of data from all offices is done on a weekly basis, while differential backup (files that have changed since the last full backup) is done on a nightly basis. The backup process is accomplished with a Fast Tape Library and backup processes are completed during off-peak hours. Two sets of tapes are taken offsite by two Information Technology (IT) staff members on a weekly basis to ensure recovery in case of failure or catastrophe.

## 4 DATA ANALYSIS

Data analysis will be conducted to summarize in situ water quality and fish counts in each sampling strata. Bounded counts or depletion estimators will be used to determine populations and linear density for each sampled unit, together with estimates of uncertainty. In addition to comparisons of fish density between sampling strata, the density estimates and uncertainties will be propagated across the unsampled areas for an overall population estimate. Exploratory multiple regression analysis will also be used to determine relationships between fish density and recorded habitat variables.

## 5 REPORTING

A data report will be prepared for use with permitting authorities that includes: date, time, and location of sampling activities; species and number of species collected; and a copy of field data sheets. Results of the winter 2009 surveys will be transmitted to TID electronically within three weeks of the survey completion (April/May 2009). A client review draft of the technical report covering the results of both winter and summer 2009 surveys will be submitted to TID by August 24, 2009. Assuming an internal and Agency review comments are received within one and three weeks of issuance of the client review and Agency review drafts, respectively, the Agency review draft will be available by September 8, 2009 and final report will be complete by October 16, 2009.

## 6 PERMITTING REQUIREMENTS

Stillwater Sciences will maintain the following permits to sample fish populations that may be present:

- NMFS Section 10(a)(1)(A) permit 1282
- California Department of Fish and Game individual Scientific Collection Permits.

A NMFS Section 10(a)(1)(A) permit 1282 has been obtained and all NMFS guidelines (e.g., notification, data gathering, preservation) will be followed if any Central Valley steelhead are captured. Under that existing NMFS permit, electrofishing is limited to an authorized incidental take of 40 juvenile $O$. mykiss and the $<5 \%$ unintentional mortality limit, and no adults. An amendment to the sampling description was submitted to NMFS on June 2, 2008 with increased take limits for handling electrofishing of 100 adults and 200 juveniles at an unintentional mortality rate of $<10 \%$. Mr. Jeffrey Jahn of NMFS will be notified at least two weeks prior to applicable sampling to confirm
sampling dates and locations. Electrofishing under an amended permit will be suspended in the event that the authorized incidental take limits were exceeded and all subsequent calibration surveys would be made by repeat dive surveys. Annual reporting will be provided to Mr. Jeffrey Jahn of NMFS by March 1, of each year.

CDFG Scientific Collecting Permits (SCPs) will be maintained for species potentially present in the project area. CDFG guidelines (e.g., notification, data gathering, and preservation) will be followed if special-status species are captured and the CDFG 24 -hr dispatch ( 916.446 .0045 ) will be notified should unrelated events result in fish kills.

No intentional mortality or removal of special-status species from the wild is included in this study plan. In the event unintentional mortality occurs beyond the take permit limits, NMFS staff will be contacted within 24 hrs and a fin-clip will be provided to the Salmonid Genetic Repository. CDFG will also be contacted to determine the disposition of the individual specimen and whether the individual may be retained for otolith analysis.

## Table of Contents

Introduction ..... 1
Study area description ..... 1
Purpose and history of study ..... 1
Methods ..... 2
Capturing study fish ..... 2
Tagging O. mykiss ..... 3
Tracking O. mykiss .....  .4
River conditions ..... 4
Results ..... 4
Capturing study fish. .....  4
Tagging O. mykiss ..... 5
Fixed station monitoring ..... 8
Mobile tracking .....  .8
Discussion ..... 11
Spawning locations of tagged adult O. mykiss. ..... 11
Use of restored river reaches by tagged adult O. mykiss. ..... 11
Migration patterns of tagged adult O. mykiss ..... 11
Literature Cited ..... 12
Appendix A ..... 13

## List of Figures

Figure 1: Location of the Tuolumne River within the San Joaquin River Basin........................................ 1
Figure 2: Map of the 2010 adult O. mykiss study area on the Tuolumne River....................................... 7
Figure 3: Release locations of tagged O. mykiss between La Grange Dam and Basso Bridge.................. 7
Figure 4: Release locations of tagged O. mykiss from Basso Bridge to Turlock Lake State Recreation Area.

Figure 5: Tuolumne River flow at La Grange (LGN) and dates of mobile tracking surveys. .9

## Introduction

## Study area description

The Tuolumne River is the largest of three major tributaries (Tuolumne, Merced, and Stanislaus Rivers) to the San Joaquin River, originating in the central Sierra Nevada in Yosemite National Park and flowing west between the Merced River to the south and the Stanislaus River to the north (Figure 1). The San Joaquin River itself flows north and joins the Sacramento River in the Sacramento-San Joaquin Delta within California's Central Valley. The Tuolumne River is dammed at several locations for generation of power, water supply, and flood control - the largest impoundment is Don Pedro Reservoir.

The lower Tuolumne River corridor extends from its confluence with the San Joaquin River to La Grange Dam at river mile (RM) 52.2. The La Grange Dam site has been the upstream limit for anadromous fish migration since at least 1871.

Figure 1. Location of the Tuolumne River within the San Joaquin River Basin.

## Purpose and history of study

Turlock Irrigation District and Modesto Irrigation District (Districts) have been required to conduct fisheries studies and monitoring under the Don Pedro Project Federal Energy Regulatory Commission (FERC) license starting in 1971. A required "Ten Year Summary Report" (TID/MID 2005) presenting results of these efforts was filed by the Districts with FERC in March 2005. FERC solicited input on the

Report and held a public meeting during 2005-2006 which led to a December 20, 2006, request from FERC for a new Tuolumne River Fisheries Study Plan (Study Plan) to be prepared by the Districts and submitted by March 20, 2007. The Study Plan was intended to address information needs under Article 58 of the Project license that were identified during the review of the Report and in subsequent discussions. The primary goals of the Study Plan were to provide continued long-term trend monitoring and to undertake studies that clarify major factors that affect and potentially limit the Chinook salmon (Oncorhynchus tshawytscha) and Oncorhynchus mykiss (O. mykiss) populations in the Tuolumne River. The Study Plan was also expected to specifically include tasks on "Steelhead Presence/Protection."

The Districts distributed a proposed Study Plan for review on February 2, 2007, and revised Study Plans that included a requested winter (January-March) adult O. mykiss tracking study were submitted by the Districts on March 20, 2007 and July 13, 2007. An Order issued by FERC on April 3, 2008, directed the Districts to conduct all of the $O$. mykiss studies identified in the Study Plan, including the adult tracking study beginning in January 2009.That task was intended to better determine habitat associations and potential spawning locations, including habitat use by $O$. mykiss adults in restored and nearby reference sites. While routine fisheries monitoring conducted by the Districts has long documented the presence of O. mykiss in the Lower Tuolumne River (TID/MID 2005), little is known about life history strategies of O. mykiss in the Tuolumne River (i.e.; habitat use, in-river migration patterns, and spawning location and timing).

Objectives of the adult $O$. mykiss acoustic tracking study include:

1. Determine spawning locations of tagged adult $O$. mykiss.
2. Document migration patterns of tagged adult $O$. mykiss.
3. Determine potential habitat use of restored river reaches and nearby reference sites by tagged adult 0 . mykiss.

This study was to begin in January 2009, and timely preparations were made by the Districts to implement the study on schedule including budgeting, contracting, equipment purchase, and requesting necessary permits and authorizations. However, necessary Endangered Species Act (ESA) take authorizations were not issued by the Agencies to permit moving forward with the study in 2009, and the study was delayed until March 2010.

## Methods

## Capturing study fish

Adult O. mykiss were targeted by hook and line sampling conducted between La Grange Dam (RM 52.2) and Turlock Lake State Recreation Area (TLSRA) (RM 42.6) during March, April, and October 2010 (Figure 2). Artificial, barbless lures or flies were used to minimize potential injury or mortality. All fish captured were placed in 38-53 L perforated containers in the river while equipment was prepared to collect biological data and for tagging if the fish was of suitable size. Prior to collection of biological data, all fish were anesthetized in a separate 53 L container using a solution of $80-90 \mathrm{mg} / \mathrm{L}$ tricanemethanesulfonate in water buffered with an equal concentration of sodium bicarbonate.

Once anesthetized, fish were identified to species, fork length was measured to the nearest millimeter and weight was measured to the nearest gram. Non-biological data recorded for each fish included time and location (GPS coordinates) of capture, habitat type at capture site, photos, and other general
conditions (i.e., weather conditions, substrate type, water temperature, turbidity, conductivity, and dissolved oxygen). Habitat unit designations were based on mapping conducted by Stillwater Sciences (2009) for the 2009 O. mykiss population surveys. Fish not selected for tagging were released immediately after necessary data was collected and they had recovered from anesthesia.

## Tagging O. mykiss

HTI X-type acoustic transmitters were used for this study. These tags operate at 307 kHz andwere programmed withtag periods ranging from 7000 to 7300 milliseconds using an HTI model 490-LP tag programmer. The separation between tag codes was 14 milliseconds. Healthy adult $O$. mykiss of suitable size were immediately tagged. The maximum permitted tag weight to body weight ratio of $3.5 \%$ was generally expected to correspond to adult $O$. mykiss greater than approximately 350 mm ( 14 in ). However, in consultation with CDFG, the maximum tag weight to body weight ratio was increased to 4\% after the first two days of sampling which corresponded to adult $O$. mykiss greater than approximately 300 mm (12 in). All fish were tagged at a mobile tagging station, which allowed all tagging to be completed near the original capture location.

Figure 2. Map of the $\mathbf{2 0 1 0}$ adult $\mathbf{O}$. mykiss study area on the Tuolumne River.

Fish were surgically implanted with acoustic transmitters according to implantation procedures outlined in Adams et al. 1998 and Martinelli et al. 1998. A ventral incision approximately 20 mm long was made anterior to the apex of the pelvic girdle. The tag was inserted into the peritoneal cavity and the incision was closed with three interrupted sutures. Typical surgery times were less than four minutes. Fish were then placed into perforated holding containers in the river to recover from anesthesia. Fish were allowed to recover for 10-15 minutes before the container was turned on its side allowing for volitional release.Function of the tag was confirmed using an HTI model 492 acoustic tag detector prior to tag insertion and again during the recovery period.

## Tracking O. mykiss

Fixed station acoustic arrays were installed near Basso Bridge (RM 47.5), the Waterford rotary screw trap site (RM 29.8), and the Grayson Rotary Screw Trap site (RM 5.2; Figure 2). Each array consisted of an acoustic tag datalogger (HTI Model 295G) attached to an omnidirectional hydrophone (HTI Model 590). The system was powered by a 12 volt deep cycle battery charged by a 3 ft by 5 ft solar panel ( 216 watt, 36 volt). These arrays were installed prior to the release of tagged fish, and were operational by February 18, 2010. A beacon tag was deployed at each site to continually document that the array was functioning properly and could detect passing tags. Data were downloaded and reviewed once per week, at minimum, to confirm proper function of the arrays, and to limit potential data loss in case of equipment failure or vandalism.

Mobile tracking was conducted by a raft outfitted with an HTI Model 295G datalogger with GPS tracking capabilities. Mobile tracking surveys consisted of actively searching for tagged fish to determine their specific locations, including macro or micro-habitat usage. The timing, frequency and location of mobile surveys were dependent on environmental conditions and detection data from fixed stations and mobile tracking. Mobile tracking surveys were also conducted within 10 days of each tagging event to confirm the location and proper function of each tagged fish.

Data recorded for each fish detected during mobile tracking included, tag code, time of detection, location of detection (GPS coordinates), surface water temperature at the hydrophone, and macro habitat unit type. Micro-habitat usage (e.g. depth, substrate, association with features such as undercut bank, woody debris, large boulder, etc.) was also evaluated by using signal strength to more precisely estimate the location of each fish. In some cases, after the general location of tagged fish was determined, snorkel and underwater video techniques were used to document fish location within the habitat unit, general behavior (spawning activity), and condition.

## River conditions

Provisional daily average flow data for the Tuolumne River at La Grange was obtained from USGS at http://waterdata.usgs.gov/ca/nwis/uv/?site no=11289650\&agency cd=USGS. Water temperature data were also obtained from hourly recording Hobo Pro v2 water temperature data loggers (Onset Computer Corporation) maintained by the Districts at five sites from below La Grange Dam (RM 51.8) to just above TLSRA (RM 42.9). At the time of this report, temperature data are available through September 27, 2010.

## Results

## Capturing study fish

During the spring period, FISHBIO staff conducted hook-and-line sampling on five days between March 23 and April 7, 2010 from La Grange (RM 50.5) to TLSRA (RM 42.6). Flows during this period ranged between 225 cfs and 650 cfs. A total of 170 . mykiss were captured, with fork lengths ranging from 225505 mm and weights ranging from $135->600 \mathrm{~g}$ (Appendix A).

The fall sampling period occurred over five days from October 15 to 28, 2010. Flows during this period ranged between 350 cfs and 550 cfs . A total of 250 . mykiss were captured, forklengths ranged between 190 mm and 540 mm and weights ranging from 77-1619 g (Appendix A).

Of the 420 . mykiss captured, 19 did not meet minimum size requirements and two were rejected for other reasons. One of the rejected fish had an old hook lodged deep in its throat, and the other had already been tagged. None of the $O$. mykiss captured were adipose fin clipped.

During the fall sampling period, five Chinook salmon smolts were incidentally captured, with fork lengths ranging from $116-170 \mathrm{~mm}$. Chinook salmon were not captured during the spring sampling. Nonsalmonid species incidentally captured during hook and line sampling included Hardhead and Striped bass (Table 1).

## Tagging O. mykiss

A total of 20 adult 0 . mykiss were successfully implanted with HTI X-type tags over two discrete periods during the spring and fall 2010 (Table 2). Tagged fish body weight ranged from 313 to 1,619 g (314-540 mm forklength). Average tag weight was $12.58 \mathrm{~g}(11.95 \mathrm{~g}$ to 13.35 g$)$, and the average tag to body weight ratio was $2.2 \%$ ( $0.74 \%$ to $3.8 \%$ ). The average surgery time (time that fish were removed from anesthesia until returned to fresh water) was 3 minutes 28 seconds, and average recovery time was 10.62 minutes ( 8.5 to 13.8 minutes). After recovery all fish were released in good condition at their original point of capture. One fish did not properly recover from tagging and, in compliance with permitting requirements, was sacrificed and provided to CDFG La Grange.

On March 23, two males ( 425 and 450 mm ), and a post-spawn female ( 505 mm ) were tagged between La Grange and Basso (Figure 3). On March 29, three female fish ( $353-368 \mathrm{~mm}$ ) were tagged between Basso and TLSRA (Figure 4). During the fall period, eight tagged fish ( $314-502 \mathrm{~mm}$ ) were captured between La Grange and Basso (Figure 3), and six ( $320-463 \mathrm{~mm}$ ) were captured between Basso and TLSRA (Figure 4).

Figure 4. Release locations of tagged O. mykiss from Basso Bridge to TLSRA.

## Fixed station monitoring

Two acoustic tagged fish were detected at fixed station arrays. Tag 7110.8 was released $1,200 \mathrm{~m}$ upstream of the Zanker fixed station array. This fish was detected 260-425 m downstream of the release location between April 1 and July 27 through mobile tracking. This fish was next detected at the Zanker receiver between August 18 at 19:50 and September 10 at 11:28. The multiple detections in this area indicate that this fish was not migrating downstream, but rather utilizing the pool habitat where the receiver is located.

The other acoustically tagged fish detected by a fixed station array was not associated with this study. The tag (6192.6) was detected passing the Grayson receiver on May 15, 2010 at 15:24 hours. This tag was implanted in a yearling 0 . mykiss from the Mokelumne River Hatchery, and was released downstream in Old River on April 16, 2010 as part of a Department of Water Resources (DWR) South Delta Temporary Barriers study (Kevin Clark, DWR, personal communication). At the time of release, this fishmeasured 265 mm and weighed 194.4 g .

## Mobile tracking

A total of 10 mobile tracking surveys were conducted between April 1 and November 1, 2010 (Table 3). Mobile tracking was limited to the reach between La Grange Dam and TLSRA, as no fish tagged for this study were detected moving past the Waterford or Grayson fixed receivers. The locations of all 20 tagged fish were confirmed within a few days after tagging, and movements of the six adult 0 . mykiss tagged during the spring were tracked from early spring through fall. Flows during this period ranged between 300 cfs and 5,520 cfs (Figure 5). Average daily water temperature near La Grange Dam (RM 51.8) ranged from 9.9-12.1 ${ }^{\circ} \mathrm{C}$, while the temperature near TLSRA (RM 42.9) ranged from 9.8-15.8 ${ }^{\circ} \mathrm{C}$ during the study period (Figure 6).

Each of the six tagged $O$. mykiss tracked from early spring through fall exhibited both upstream and downstream movement. The distance between the most downstream detection and most upstream detection for each fish ranged from 145 m to $5,715 \mathrm{~m}$, with four of the six fish covering a range of approximately 600 m to $1,000 \mathrm{~m}$ (Table 3).

The expected life of the HTI X-tags was approximately 300 days, but mobile tracking data suggested that of five of the six tags released during the spring expired within 219 days. As of November 1, one tag was still functioning. Tag life was likely reduced by the cool temperatures in the study reach. The tags used during the fall tagging period are LX-type tags, which feature an updated processor that is expected to increase the life of these tags.

Table 3. Distance between mobile tracking detections by survey date (upstream(+), downstream(-), not detected(ND)).

| Tag ID | Distance Between Detections (m) |  |  |  |  |  |  |  |  |  | Total Range |

Figure 5. Tuolumne River flow at La Grange (LGN) and dates of mobile tracking surveys.

Figure 6. Tuolumne River average daily water temperatures between La Grange Dam and TLSRA.

Tag 7012.8 was implanted in an adult $O$. mykiss captured in habitat unit NSO 033 at RM 49.2 on March 23. During all mobile tracking surveys conducted between April 1 and June 15, this tag was detected within 130 m of the original release location. On July 7 , this tag was detected 460 m upstream of the original location, but was not detected during any of the subsequent mobile tracking surveys. However, during hook and line sampling on October 20, an adult $O$. mykiss of similar size and with a surgery scar and a single suture still intact, was captured near the original capture location of 7012.8. The identity of the fish could not be confirmed since a signal was not detected. It is believed that the tag died sometime after July 7 when it was last detected, and there were no indications that the tag had been expelled from the fish. Also, had the tag been expelled, it would have still likely been detected during mobile tracking surveys.

Tag 7054.8 was implanted in an adult 0 . mykiss captured in the run directly upstream of the HWY 59 bridge (NSO 024) on March 23. This tag was detected 635 m downstream of the original capture location on April 1. During April and May it was detected moving back upstream towards the original capture location before moving downstream during June through September, returning to the approximate location where it was detected on April 1.

Tag 7068.8 was implanted in an adult 0 . mykiss captured in the run directly upstream of the HWY 59 bridge (NSO 024) on March 23, and this fish exhibited the longest range of movement. Tag 7068.8 was detected $2,590 \mathrm{~m}$ downstream on April 1, and was detected within 30 m upstream and 150 m downstream of this location from April 26 through July 7. On July 27, this tag was found to have returned upstream to the habitat unit where the fish was originally captured. This fish continued to move upstream and was detected directly below the La Grange powerhouse on September 27. During the October and November surveys, this fish was again detected moving downstream and was found 880 m and $1,290 \mathrm{~m}$ below the original capture location.

Tag 7110.8 was implanted in an adult $O$. mykiss captured in the run below Basso Bridge (NSO 059) on March 29. Between April 1 and July 27, this tag was detected in a riffle/run sequence (NSO 065-066) located 260 to 425 m downstream of the initial point of capture. On September 9, this tag was detected in a run habitat unit approximately 400 m downstream (NSO 067) of the lower boundary of the riffle/run sequence (NSO 065-066).

Tag 7124.8 was implanted in a female adult $O$. mykiss captured in the pool at NSO 087 on March 29, and this fish exhibited the shortest range of movement. On April 1 and 27, this tag was detected within this same pool (NSO 87). Between May 20 and July 27 this tag was detected in a riffle (NSO 089) 95 to 145 m downstream of the point of capture. On September 9 , this tag was detected back in the pool where it was originally captured.

Tag 7194.8 was implanted in a female adult O. mykiss captured in the pool at NSO 087 on March 29. On April 1 and 27, this tag was detected within this same pool (NSO 87). On May 20 and June 15 this tag was detected approximately 600 m upstream in another pool directly below the mouth of Peaslee Creek (NSO 081). By July 7 this fish had returned to the pool where it was originally captured (NSO 87), and remained here through at least July 27. On September 9, the tag was detected in a run (NSO 083) approximately 200 m upstream.

## Discussion

## Spawning locations of tagged adult O. mykiss

Peak spawning activity likely occurs during January through March (McEwan 1996), and initiation of this study was delayed until March 2010 due to permitting issues, which precluded the opportunity to determine spawning locations of tagged O. mykiss during winter 2010. However, possible O. mykiss redds were identified in riffle NSO 033, and a large female O. mykiss, which appeared to have recently spawned, was captured nearby in the same unit suggesting that it may have spawned at this location.

Adult O. mykiss tagged during fall 2010 will be tracked during the expected winter spawning period (January-March 2011). It is recommended that tagging should occur during fall 2011 to ensure adequate tag life (estimated at 6-12 months) for tracking through the expected spawning period during JanuaryMarch 2012, to avoid tagging ripe individuals, and to provide adequate recovery time prior to the expected spawning period.

## Use of restored river reaches by tagged adult O. mykiss

During 2010, adult O. mykiss were not captured or detected in restored reaches of the Tuolumne River. However, two fish were captured and tagged (tags 7054.8 and 7068.8) just downstream of the CDFG gravel introduction riffle 1A/1B (NSO 18-22) in a unit identified as sensitive 0 . mykiss habitat (McBain\&Trush 2004). While these fish were not detected within the restoration reach, they were repeatedly detected in the same location, and may have been attracted to this area by features associated with the restored habitat such as increased invertebrate production.

A total of 47 sites have been identified as sensitive O. mykiss habitat between La Grange Dam and Roberts Ferry Bridge (McBain\&Trush 2004), and $85 \%$ of the adult O. mykiss tagged during 2010 were detected in these locations. However, adult 0 . mykiss were only detected in $19 \%(n=8)$ of the sensitive habitat sites surveyed.

## Migration patterns of tagged adult O. mykiss

During 2010, movements of six tagged adult $O$. mykiss were tracked from early spring through fall under highly varying flow conditions due to flood control operations. Each of the six tagged O. mykiss tracked from early spring through fall exhibited both upstream and downstream movements, with no apparent correlations to flow or water temperature. However, conclusions are limited by the small sample size and highly variable instream conditions during the study period. All tagged O. mykiss remained in the Tuolumne River during the 2010 monitoring period.

Operation of fixed station acoustic arrays also provided information on straying of hatchery produced 0 . mykiss into the Tuolumne River. An acoustically tagged Mokelumne River Hatchery produced yearling O. mykiss released in Old River as part of DWR's South Delta Barriers Study was detected in the Tuolumne River at Grayson, and another five tagged O. mykiss from the same study releases were detected entering the Stanislaus River, indicating that at least $2 \%$ of the fish released strayed into the San Joaquin Basin tributaries. Straying of hatchery produced O. mykiss has also been documented at the Stanislaus River Weir.

## Introduction

The California Department of Fish and Game (CDFG) has reported salmon escapement estimates on the Tuolumne River since 1940 (Fry 1961). Estimates of adult fall-run Chinook salmon escapement have varied from about 100 to 130,000 from 1940 to 1997 (mean: 18,300; median: 7,100) (Ford and Brown 2001). Over the last decade, estimates of adult fallrun Chinook salmon have ranged from a high of 17,873 in 2000 (Vasques 2001) to a low of 211 in 2007 (Blakeman 2008). Most, estimates of fall-run population size were obtained using carcass surveys (some weir counts were made at Modesto in the 1940's). While carcass surveys provide essential data to document the timing and distribution of spawning, population estimates from mark-recapture models are prone to bias if rigid assumptions are not met. Alternatively, resistance board weirs provide direct counts that are not subject to the same biases. Weirs also provide precise migration timing information, while carcass surveys provide essential data to document the timing and distribution of spawning. Resistance board weirs have been widely used in Alaska to estimate salmonid escapement since the early 1990's (Tobin 1994), and a weir has been operated successfully on the nearby Stanislaus River since 2003.

The Tuolumne River weir project was initiated during fall 2009, and the Turlock Irrigation District (TID), Modesto Irrigation District (MID), and the City and County of San Francisco jointly supported this effort. The objectives of the Tuolumne River Weir Project include:
$>$ Determine escapement of fall-run Chinook salmon and steelhead to the Tuolumne River through direct counts.
$>$ Document migration timing of adult fall-run Chinook salmon and steelhead in the Tuolumne River and evaluate potential relationships with environmental factors.
> Determine size and gender composition of returning adult salmon population.
$>$ Estimate hatchery contribution to spawning population
$>$ Document passage of non-salmonids

## Study Area

The Tuolumne River is the largest tributary to the San Joaquin River, draining a 1,900 square-mile watershed that includes the northern half of Yosemite National Park (McBain and Trush 2000). The Tuolumne River originates in the central Sierra Nevada Mountains and flows west between the Merced River to the south and the Stanislaus River to the north (Figure 1). The San Joaquin River flows north and joins the Sacramento River in the Sacramento-San Joaquin Delta within California’s Central Valley.

The Tuolumne River is dammed at several locations for power generation, water supply, and flood control - the largest impoundment is Don Pedro Reservoir. The lower Tuolumne River corridor extends from its confluence with the San Joaquin River to La Grange Dam at river mile (RM) 52.2. The La Grange Dam site has been the upstream limit for anadromous migration since 1871. The spawning reach of the Tuolumne River has been defined as extending 28.1 miles downstream of La Grange Dam to RM 24.1 (O’Brien 2009).

The weir is located at RM 24.5 (Figure 1), and this site was selected for weir operation because it is located below the typical downstream boundary of the CDFG spawning surveys.

Site selection was also based on operational criteria that include water velocity, channel width, bank slope, channel gradient, channel uniformity, and substrate type.

Figure 1. Map of the Tuolumne River displaying the location of the Tuolumne River Weir and other key points of interest.

## Methods

A resistance board weir (Tobin 1994; Stewart 2002, 2003) and Vaki Riverwatcher fish counting system (Vaki system) were installed in the Tuolumne River at RM 24.5 on September 9, 2010, monitoring continued until December 1, 2010 when the weir and the Vaki were removed in anticipation of high flow, due to flood control releases, that were expected to exceed the operational threshold (i.e. >1,300 cfs; Figure 8). The weir was not reinstalled, as flows remained high throughout the remainder of the fall-run Chinook salmon migration period.

Some modifications were made to the weir design prior to the 2010 season to facilitate passage of fish through the weir. Modifications included: removal of the upstream trap (Figure 2), removal of the fyke at the entrance to the camera viewing lane (Figure 3); removal of a nine foot section of substrate rail; removal of three resistance board panels (i.e. nine feet); installation of two floating bulkheads; and installation of a large nine foot wide by five foot high aluminum fyke (Figure 4). Since the upstream trap was removed no trapping was conducted this season.

Figure 2. Tuolumne River Weir upstream trap and camera box before modifications (left photo) and camera box (upstream trap removed) after modifications (right photo).

Figure 3. Tuolumne River camera viewing lane before modifications. Circle indicates fyke that was removed.

Figure 4. Tuolumne River Weir passage chute before modifications (left photo) and after modifications (right photo).

Weir and Vaki components were inspected and cleaned daily or more frequently when debris loads were heavy. The boat passage portion of the weir was briefly over-topped (submerged) on nine occasions due to debris, and the entire length of the weir was briefly over-topped on October 11, 2010 (Table 1). Maintenance procedures generally followed guidelines found in Tobin (1994) and Stewart (2002, 2003), although slight adjustments were made to accommodate site-specific attributes of the Tuolumne River Weir. For example, sealed plastic barrels were used for additional floatation during periods of high flows (Figure 5).

Figure 5. Photograph of the flotation barrels lining the underneath of the resistance weir.
In conjunction with the weir, a Vaki Riverwatcher fish counting system (Vaki system) was used during the majority of the study period to monitor fish passage without the need to capture or handle fish. The Vaki system is comprised of three main components: an infrared scanner, a digital video camera with lights, and a computer system (Figure 6).

Figure 6. Left: Photograph of the Vaki Riverwatcher infrared scanner looking from upstream to downstream at the upstream side of the scanner plates. Center: Example of the riverwatcher camera and lights. Right: Tuolumne Weir Vaki Riverwatcher computer system and job box.

The Vaki infrared scanner was attached to a fyke at an opening in the weir (Figure 6), and data was relayed to a computer system that generated infrared silhouettes and video clips of passing objects (Figure 7). The system also recorded the time, speed, and direction of passage, as well as the depth of the passing object.

The Riverwatcher estimates length based on the depth (body depth) of the fish. A userdefined coefficient was derived from a body depth to total length ratio from measurements of trapped fish and carcasses. The user-defined coefficient is applied to the Riverwatcher measured depth to estimate total length. The coefficient is derived by the following equation:

$$
l=\frac{t l}{d}
$$

where, $l$ is the length coefficient, $t l$ is the total length, and $d$ is the body depth of the measured fish. Total length is estimated by the following equation:

$$
L=D \times l
$$

where, $L$ is the estimated total length, $D$ is the body depth measured by the Riverwatcher, and $l$ is the length coefficient. Only trapped fish were used for Chinook salmon ratio measurements.

Data from the Vaki computer was downloaded and reviewed daily during the peak migration periods. Infrared silhouettes were used in conjunction with digital video to identify passing objects (Figure 8). Video aids in the determination of gender, total length, presence/absence of adipose fin, distinguishing salmonids to species, and provides the only evidence of the condition of the fish.

Figure 7. Example of silhouette images produced from both sets of scanner diodes (one image from one set of diodes is displayed in blue and the other is displayed in red). The left set of images is an example of a typical salmonid silhouette and the right set of images is an example of a poor salmonid silhouette.

Figure 8. Top image is an example of a typical salmonid silhouette and the bottom image is a screen capture from a video clip of the same fish that is displayed in the top image. Note: Video clips are a higher quality image than the screen capture.

After each passage was identified to species, data were exported into an excel spreadsheet. The daily passage counts consisted of net upstream passages (upstream passages -
downstream passages). Other information obtained from video clips was recorded including whether the presence/absence of an adipose fin (ad-clipped; Figure 9), fish condition, and gender.

Video provide the only means by which Chinook salmon and $O$. mykiss may be distinguished, and the identity of many species is uncertain based on infrared silhouettes alone. The quality of video is reduced when turbidity increases and can preclude identification of fish to species.

Figure 9. Example of a silhouette image and screen capture from a video clip of the same Chinook salmon that has a clipped adipose fin (ad-clip). Note: Video clips are a higher quality image than the screen capture.

Physical data collected during each weir check included water temperature ( ${ }^{\circ} \mathrm{F}$ ), dissolved oxygen (mg/L), turbidity (NTU), weather conditions (RAN = rain, CLD = cloudy, CLR = clear, $\mathrm{FOG}=\mathrm{fog}$ ), and water velocity ( $\mathrm{ft} / \mathrm{s}$ ) measurements at the opening of the livebox. Instantaneous water temperature and dissolved oxygen were recorded using an Exstick II model DO600 Dissolved Oxygen Meter (Extech Intruments Corporation). Hourly water temperature data was logged using an iBCod type G submersible data logger (Alpha Mach, Inc.). Turbidity was recorded using a model 2020e Turbidimeter (LaMotte Co.), and water
velocity was measured using a digital Flow Probe model FP-101 (Global Water Instrumentation, Inc.). Tuolumne River flow was also downloaded from the California Data Exchange Center (CDEC).

Visual assessments in a half-mile reach upstream and downstream of the weir were conducted to monitor potential migration delay or digging activity. Boat surveys were conducted on Monday, Wednesday and Friday of each week during September and daily from October 1 through December 1. A "stacking ratio" was calculated using the number of salmon observed downstream of the weir and the number of salmon recorded by the Riverwatcher passing the weir during a three-day period to identify potential migration delays and if the ratio exceeded 1.15, three panels will be removed from the weir until CDFG allowed normal operations to resume.

At the request of California Department of Fish and Game an overhead video system was installed to observe fish behavior associated with the weir (Figure 10); however, the overhead video equipment did not give us high enough quality imagery to successfully make any observations. However, only one fish was observed downstream of the weir during visual assessments from a boat, resulting in a maximum stacking ratio of 0.07 for the season, which is substantially less than the 1.15 threshold.

Figure 10. Overhead camera system circled in yellow.

## Results

## Chinook salmon abundance and migration timing

Between September 9, 2010 and December 1, 2010, the Riverwatcher detected 785 adult fallrun Chinook salmon as they passed upstream of the weir (Figure 11). Due to flood control releases on the Tuolumne River monitoring ended on December 1.

Daily passage ranged between zero and 50 Chinook (Figure 11). Most Chinook salmon passage significantly decreased during the day (1000 hours - 1559 hours), increased at dusk and night (1600 - 2159 hours and 2200 - 0359 hours; respectively), and remained high during the dawn ( $0400-0959$ hours) (ANOVA: $F=8.71, P=0.01 E 03$ ) (Figure 12).

During 2009, 17.6\% of fall-run Chinook salmon passed between December 1 and December 31, 2009. If it is assumed that the same proportion of Chinook salmon passed during the same time period in 2009, it is estimated that an additional 138 adult fall-run Chinook salmon may have passed the weir site undetected.

Figure 11. Daily upstream Chinook passage recorded at the Tuolumne River Weir in relation to daily average flows (cfs) recorded in the Tuolumne River at La Grange (LGN) and Modesto (MOD) between September 9, 2010 and December 31, 2010 [Data source: CDEC - http://cdec.water.ca.gov].

Figure 12. Chinook salmon passage in 6-hour time blocks. Diel Chinook salmon passage was not significant among the different time periods (ANOVA: $F=8.71, P=0.01 E 03)$.

One post-spawn male fall-run Chinook salmon carcass was recovered from the top of the weir and one ripe (pre-spawn) male Chinook carcass was impinged between the resistance weir and the substrate on September 22, 2010 (Table 2).

Table 2. Post-spawn and pre-spawn (ripe) fall-run Chinook salmon carcasses recovered from the Tuolumne River Weir between September 9, 2010 and December 1, 2010.

| Species | Date | TL (mm) | Adipose Fin Clip | Sex | Post-spawn |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Chinook salmon | $9 / 22 / 10$ | 1,010 | No | Male | No |
| Chinook salmon | $11 / 11 / 10$ | 760 | No | Male | Yes |

## Chinook salmon gender and size

Total fall-run Chinook salmon passage was composed of $40 \%$ male ( $\mathrm{n}=317$ ), $42 \%$ female ( n $=326$ ), and $18 \%$ unknown ( $\mathrm{n}=142$ ). Mean total length for Chinook salmon upstream passages were: $708 \mathrm{~mm}(\mathrm{n}=398)$ for male, $693 \mathrm{~mm}(\mathrm{n}=387)$ for female, $550 \mathrm{~mm}(\mathrm{n}=194)$ for unknown; and 670 mm for all Chinook combined (Table 3). While mean lengths were similar for male and female salmon, the length frequency distributions differed with males predominately the $550-600 \mathrm{~mm}$ size class and females were predominately the $750-800$ mm size class (Figure 13).

## Origin of Chinook salmon production

Adipose fin clips, suggesting hatchery origin, were observed in $32 \%$ of Chinook counted at the Tuolumne River weir during 2010. Although releases of hatchery origin Chinook have not been made in the Tuolumne River in recent years, straying from other basins is common as evidenced by the recovery of coded wire tags during annual carcass surveys.

Table 3. Fall-run Chinook salmon upstream passage data from September 9, 2010 through December 1, 2010 (upstream passage counts only, data are not directly comparable to net passage). Parenthesis indicate range.

| Sex - Adipose fin clip | Mean TL $(\mathrm{mm})$ | $95 \%$ CI $(\mathrm{mm})$ | n |
| :---: | :---: | :---: | :---: |
| Male - No | $748(472-1,033)$ | $748 \pm 17$ | 243 |
| Male - Yes | $650(480-943)$ | $650 \pm 18$ | 128 |

$671 \pm 10$
984

Figure 13. Length frequency of male and female fall-run Chinook salmon passage (upstream passage counts only, data are not directly comparable to net passage).
O. mykiss

No $O$. mykiss were recorded passing through the weir between September 9, 2010 and December 1, 2010.

## Non-salmonids

There were 11 other species identified passing the weir including American shad (Alosa sapidissima), common carp (Cyprinus carpio), channel catfish (Ictalurus punctatus), goldfish (Carassius auratus), largemouth bass (Micropterus salmoides), Sacramento blackfish (Orthodon microlepidotus), Sacramento pikeminnow (Ptychocheilus grandis), Sacramento sucker (Catostomus occidentalis), smallmouth bass (Micropterus dolomieu), striped bass (Morone saxatilis), white catfish (Ictalurus catus); as well as unknown species of black bass (Micropterus spp.), catfish (Ameiurus spp. and Ictalurus spp.), and sunfish (Lepomis spp.) (Table 4). There were 67 passages that were identified as fish, but could not be identified to species.

Table 4. Incidental species passage data from September 9, 2010 through December 1, 2010 (upstream passage counts only, data are not directly comparable to net passage). Parenthesis indicates range.

| Native Species | Mean TL $(\mathrm{mm})$ | Date Range | Total Passage |
| :--- | :---: | :---: | :---: |
| Sacramento blackfish | $359(218-582)$ | $9 / 14 / 10-11 / 30 / 10$ | 14 |
| Sacramento pikeminnow | $272(208-374)$ | $9 / 13 / 10-11 / 30 / 10$ | 63 |
| Sacramento sucker | $390(224-767)$ | $9 / 10 / 10-12 / 1 / 10$ | 141 |
| Non-native Species | Mean TL $(\mathrm{mm})$ | Date Range | Total Passage |
| American shad | $250(247-253)$ | $9 / 17 / 10-9 / 19 / 10$ | 2 |
| Common carp | $466(167-914)$ | $9 / 12 / 10-12 / 1 / 10$ | 572 |

## Environmental Conditions

Between September 9, 2010 and December 1, 2010 daily average flow at La Grange (LGN; RM 51.8) ranged between 304 cfs and 860 cfs ( 399 cfs season average). After the weir was removed, flows ranged between 1,890 cfs and 5,350 cfs through December 31, 2010. Daily average flow at Modesto (MOD; RM 17) ranged between 417 cfs and 968 cfs ( 502 cfs season average) during weir monitoring and from 2,530 cfs to 7,100 cfs during December after the weir was removed (Figure 11).

Instantaneous water temperatures measured at the weir ranged between $48.3^{\circ} \mathrm{F}$ and $70.1^{\circ} \mathrm{F}$ ( $59.7^{\circ} \mathrm{F}$ season average; Figure 14). Instantaneous turbidity ranged between 0.22 NTU and 3.48 NTU (1.35 NTU season average; Figure 15), and instantaneous dissolved oxygen ranged between $7.47 \mathrm{mg} / \mathrm{L}$ and $10.87 \mathrm{mg} / \mathrm{L}(8.78 \mathrm{mg} / \mathrm{L}$ season average; Figure 16).

Figure 14. Daily upstream Chinook passage recorded at the Tuolumne River Weir in relation to instantaneous water temperature $\left({ }^{\circ} F\right)$ at the weir and daily average water temperature $\left({ }^{\circ} F\right)$ at Modesto (MOD) between September 9, 2010 and December 1, 2010 [Data source: CDEC http://cdec.water.ca.gov].

Figure 15. Daily upstream Chinook passage recorded at the Tuolumne River Weir in relation to instantaneous turbidity (NTU) between September 9, 2010 and December 1, 2010.

Figure 16. Daily upstream Chinook passage recorded at the Tuolumne River Weir in relation to instantaneous dissolved oxygen (mg/L) between September 9, 2010 and December 1, 2010.

## Discussion

The Vaki Riverwatcher detected 785 fall-run Chinook salmon during 2010, which represents a substantial increase over the previous year (Table 4). It is estimated that an additional 138 adult fall-run Chinook salmon may have passed between December 1 and December 31 when the weir was removed due to elevated flows (due to flood control releases) that exceed the operational range of the weir. Although there were no apparent relationships between migration timing and turbidity or dissolved oxygen during 2010; there appeared to be an increase in passage once temperature decreased below $60^{\circ} \mathrm{F}$ which coincided with a small
increase in flow due to managed pulse flow releases for fall-run Chinook salmon migration attraction.

Table 4. Annual adult Chinook salmon passage counts by run-type and range of dates that adult Chinook salmon passed the Tuolumne River Weir.

| Year | Run Type | Passage Date Range | Total Passage Count |
| :---: | :---: | :---: | :---: |
| 2010 | Fall | September 9 - December 1 | 785 |
|  | Unknown | No sample | - |
| 2009 | Fall | September 22 - December 31 | 264 |
|  | Unknown | January 1 - February 10 | 31 |

Approximately 31\% of the Chinook salmon observed at the Tuolumne River weir were two-year-old fish ( $\leq 600 \mathrm{~mm} \mathrm{TL}$ ), and the majority ( $56 \%$ ) of these were males. Two-year-old males are commonly known as jacks and these fish may contribute up to $67 \%$ of the run in some years (Moyle 2002). Jacks are widely used in escapement prediction models (Beer et. al. 2006) where a large return of jacks suggests an increase in escapement for the following year.

The Tuolumne River Chinook salmon population is not supplemented with hatchery fish however, the 2010 fall-run was comprised of $33 \%$ ad-clipped Chinook (suggesting hatchery origin). Given that roughly $75 \%$ of hatchery fish are not clipped and assuming that unclipped and clipped hatchery fish are equally likely to stray, it is likely that quite a few unclipped hatchery fish also entered this river in 2010. In previous years, straying of fish released off-site into San Pablo Bay has been estimated to be as high as 70\% (CDFG \& NMFS 2001) and may be found to be even greater once analysis of CWT data for the most recent years are completed.

Escapement estimates from weir counts and carcass survey differed greatly during 2010, demonstrating the importance of weir monitoring in this system. At the Tuolumne weir, 791 fall-run Chinook salmon were counted while the preliminary adjusted Petersen estimate based on carcass survey data was only 540 fall-run Chinook salmon (CDFG GrandTab). Similarly, carcass surveys also underestimated Chinook salmon escapement to the Stanislaus River during the September to December 2010 period and the Tuolumne River during the previous year. Although the weir was removed prematurely due to elevated flows, the ability for researchers to recover tagged-carcasses during carcass surveys violates assumptions that the adjusted Petersen model must adhere to establish any confidence in the escapement estimate.

In addition to providing information on migrating adult fall run Chinook salmon, the weir also provided information on the movement and sizes of 11 non-salmonid species observed passing the weir. Most (81\%) of the non-salmonid species were non-native, any many of the non-native species are known to prey on juvenile Chinook salmon (e.g. largemouth bass, smallmouth, striped bass, and catfish) (Tabor et. al. 2007). Year-round monitoring could provide more insight into Chinook salmon run dynamics on the Tuolumne River as well as abundance indicators for predatory fishes.

Although we were unable to observe fish passage behavior with the overhead video monitoring the calculated stacking ratio and visual assessments downstream of the weir suggest that the fish passage modifications provided improved fish passage conditions at the weir.
