1. Don Pedro Reservoir Maximum
- |    |                     |                          |                     |
|----|---------------------|--------------------------|---------------------|
| a) | Elevation:          | 812.54 Feet              | 830 Feet            |
| b) | Storage:            | 1,813,321 Acre-Feet      | 2,030,000 Acre-Feet |
| c) | Inflow (4 hrs Avg.) | 6,677 Cubic Feet/ Second |                     |
2. Release From Don Pedro (3 Hr Avg.) :
- |    |   |        |                    |
|----|---|--------|--------------------|
| a) | Release to River @ La Grange:             | 9,552  | Cubic Feet/ Second |
| b) | Release to TID Main Canal at La Grange fo | 953    | Cubic Feet/ Second |
| c) | Release to MID Main Canal at La Grange:   | 337    | Cubic Feet/ Second |
| d) | Total Release from Don Pedro:             | 10,842 | Cubic Feet/ Second |
3. Turlock Lake Reservoir Maximum Winter
- |    |                  |                        |                  |
|----|------------------|------------------------|------------------|
| a) | Elevation:       | 230.9 Feet             | 237 Feet         |
| b) | Storage:         | 20,491 Acre-Feet       | 34,400 Acre-Feet |
| c) | Inflow (24 hrs)  | 774 Cubic Feet/ Second |                  |
| d) | Release (24 hrs) | 658 Cubic Feet/ Second |                  |
| e) | Inflow (4 hrs)   | 826 Cubic Feet/ Second |                  |
4. Flow at 9th Street
- |    |            |                          |  |
|----|------------|--------------------------|--|
| a) | Elevation: | 53.97 Feet               |  |
| b) | Flow:      | 9,760 Cubic Feet/ Second |  |
5. Flow on Dry Creek  
Crab Tree Road: 18 Cubic Feet/ Second
6. U.S. National Weather Service watershed forecast for next 6 days ending:
- |    | Inches | Freezing Level | Day |
|----|--------|----------------|-----|
| a) | 0.2    | 9,400          | Mon |

| c) | 0.3    | 6,500          | Wed |
| d) | 0.0    | 6,700          | Thu |
| e) | 0.7    | 7,500          | Fri |
| f) | 0.7    | 6,100          | Sat |
|    | 3.2    |                |     |

7. Information

Visit <http://www.tid.com/flows> for up to date information

**Notes: Additional Information****NWS Comments: Monday, March 20, 2017 3:58 AM****...Two Significant Storms to Impact the Area This Week...**

Updates in Yellow

**Impacts**

- Slick roadways, potential for increased traffic accidents and longer travel times next week
- Mountain travel delays and possible chain controls north of Kings Canyon
- Strong gusty winds on Tuesday may bring localized power outages and downed trees.
- Thunderstorms may bring locally heavy rainfall, hail and frequent lightning

**Forecast Confidence**

- **High for Today - Wednesday Weather System**
- **Medium for thunderstorms on Tuesday; High for Wednesday thunderstorms**
- **Medium for Friday - Saturday Weather System**

**Timing & Strength**

- **Tonight - Wednesday:** Widespread precipitation with strong gusty winds. Snow levels around **8000** feet on Monday Night into Tuesday, then lowering to 5000 feet on Wednesday. Afternoon/evening thunderstorms possible on Tuesday, though more favorable on Wednesday.
- **Friday - Saturday:** Another storm system expected to arrive Friday with widespread significant precipitation possible.

**Weather Summary**

Unsettled weather is anticipated to return to the region **tonight** and continue through Wednesday. There is a chance of afternoon and evening thunderstorms on Tuesday and again on Wednesday; some could become strong, especially on Wednesday, due to colder, more unstable air. **A wetter system is expected to move in on Friday and continue into Saturday, with thunderstorms once again possible on Saturday.**

**NWS will continue to provide updates as the situation develops.**

Don Pedro	0.00	0.00	0.00	0.00	0.00	0.00	0.00

\* Computed Natural Flow is a calculated value representing what the flow in the river at La Grange would be without human diversion, storage, or release. Due to the nature of the calculation, this value may be negative.

\*\* Inflow is a calculated value representing the flow of water into a reservoir. Inflow to a reservoir is not necessarily equal to the Computed Natural Flow. Due to the nature of the calculation, this value may be negative.

**Note:** cfs is a rate of flow in cubic feet per second; a flow of 1 cfs over a 24-hour period (cfs/day) ≈ 1.98 acre-feet (AF); mgd is a rate of flow in million gallons per day (megagallons per day); a flow rate of 1 mgd ≈ 1.55 cfs; a flow of 1 mgd over a 24-hour period ≈ 3.1 AF.

### 6. Atmospheric River Prediction

#### a. Integrated Water Vapor Transport (IVT) Forecast

The plume diagram above represents the integrated water vapor transport (IVT) forecast for each of the 20 perturbed GFS ensemble models (thin gray lines), the unperturbed GFS control forecast (black line), the 20-member ensemble mean (green line), and the maximum ensemble value at that forecast hour (red line) and minimum ensemble value at that forecast hour (blue line). The white shading represents the +/- 1 standard deviation forecast from the ensemble mean.

b. Ensemble Mean of Coastal kg/m/s

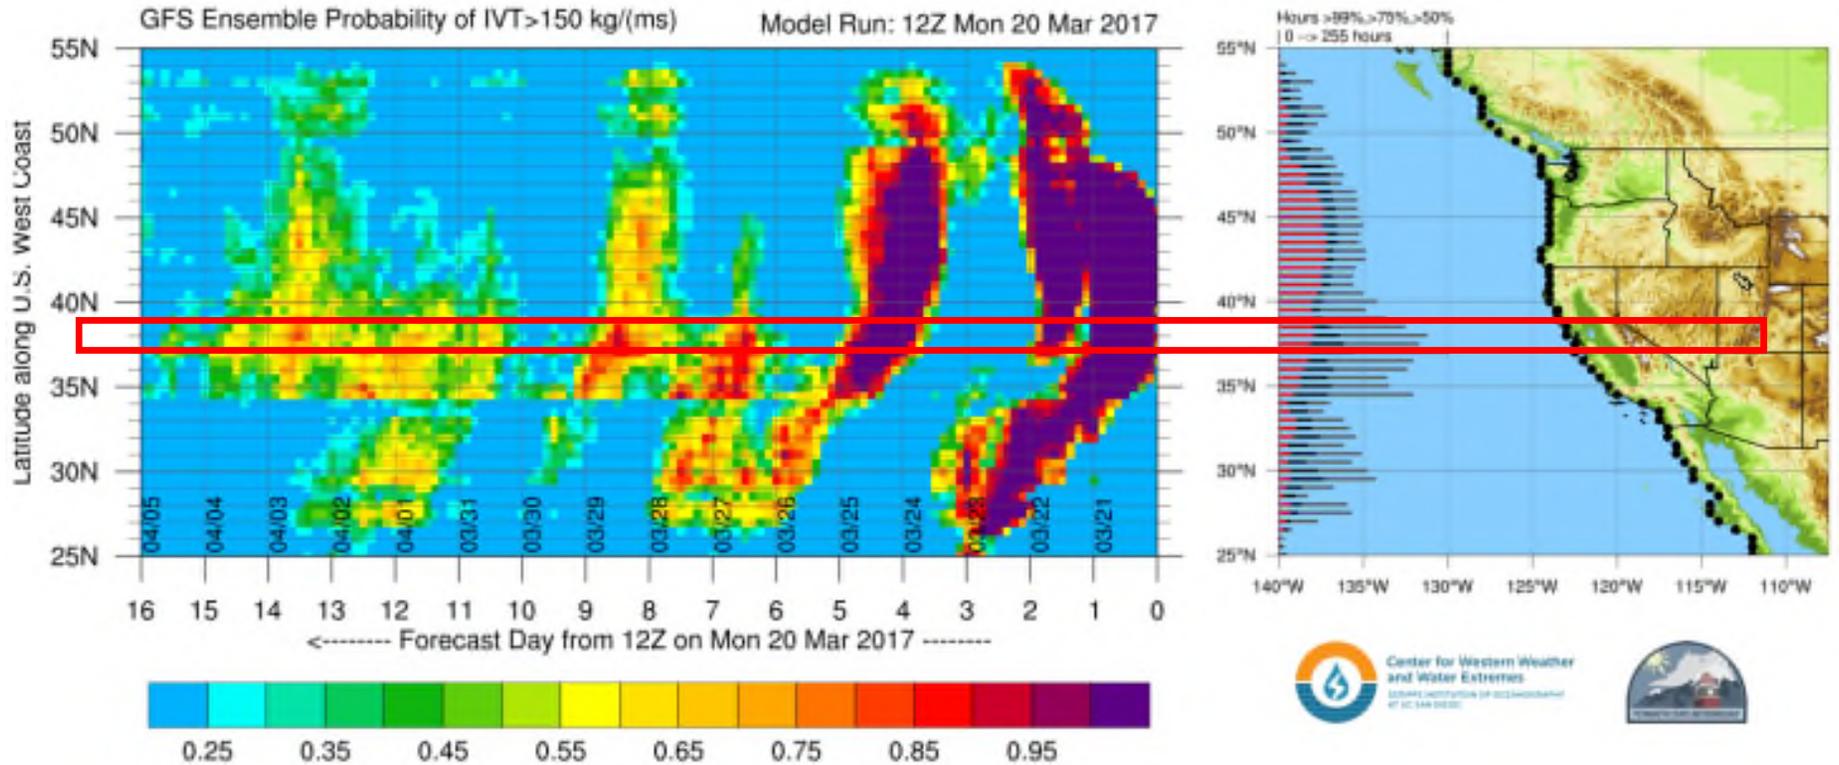

What does the diagram show?

The magnitude of integrated vapor transport (IVT) at different latitudes along the U.S. West Coast from "today" through the next 16 days at 3-hour increments. The landfall locations are the black dots in the right-most panel. The IVT magnitude is shaded on a scale from <200 kg/m/s to >1000 kg/m/s. The right map-panel graphically depicts the total 16-day time-integrated IVT for that location in millions of kg/m.

These contain the probability of having "atmospheric river" conditions, (i.e., high water vapor content) at different latitudes along the U.S. West Coast from "today" through the next 16 days at 3-hour increments. Evidence suggest that IVT magnitudes >250 kg/m/s are typically consistent with "AR conditions", whereas IVT magnitudes >500 kg/m/s are consistent with strong ARs. The values of 150 kg/m/s should be used for inland locations. The landfall locations are the black dots in the right-most panel. The probability is shaded on a scale from 0% (blue) to 100% (purple).

The diagram also graphically depicts the number of hours a location along the coast may expect to see AR conditions at different fraction thresholds: Gray bars for number of hours with a probability >50%, black bars for number of hours >75%, and red bards for number of hours >99%. The higher this number, the longer AR conditions are likely and the more precipitation may be expected!

c. Ensemble Probability of Coastal IVT > 150 kg/m/s,

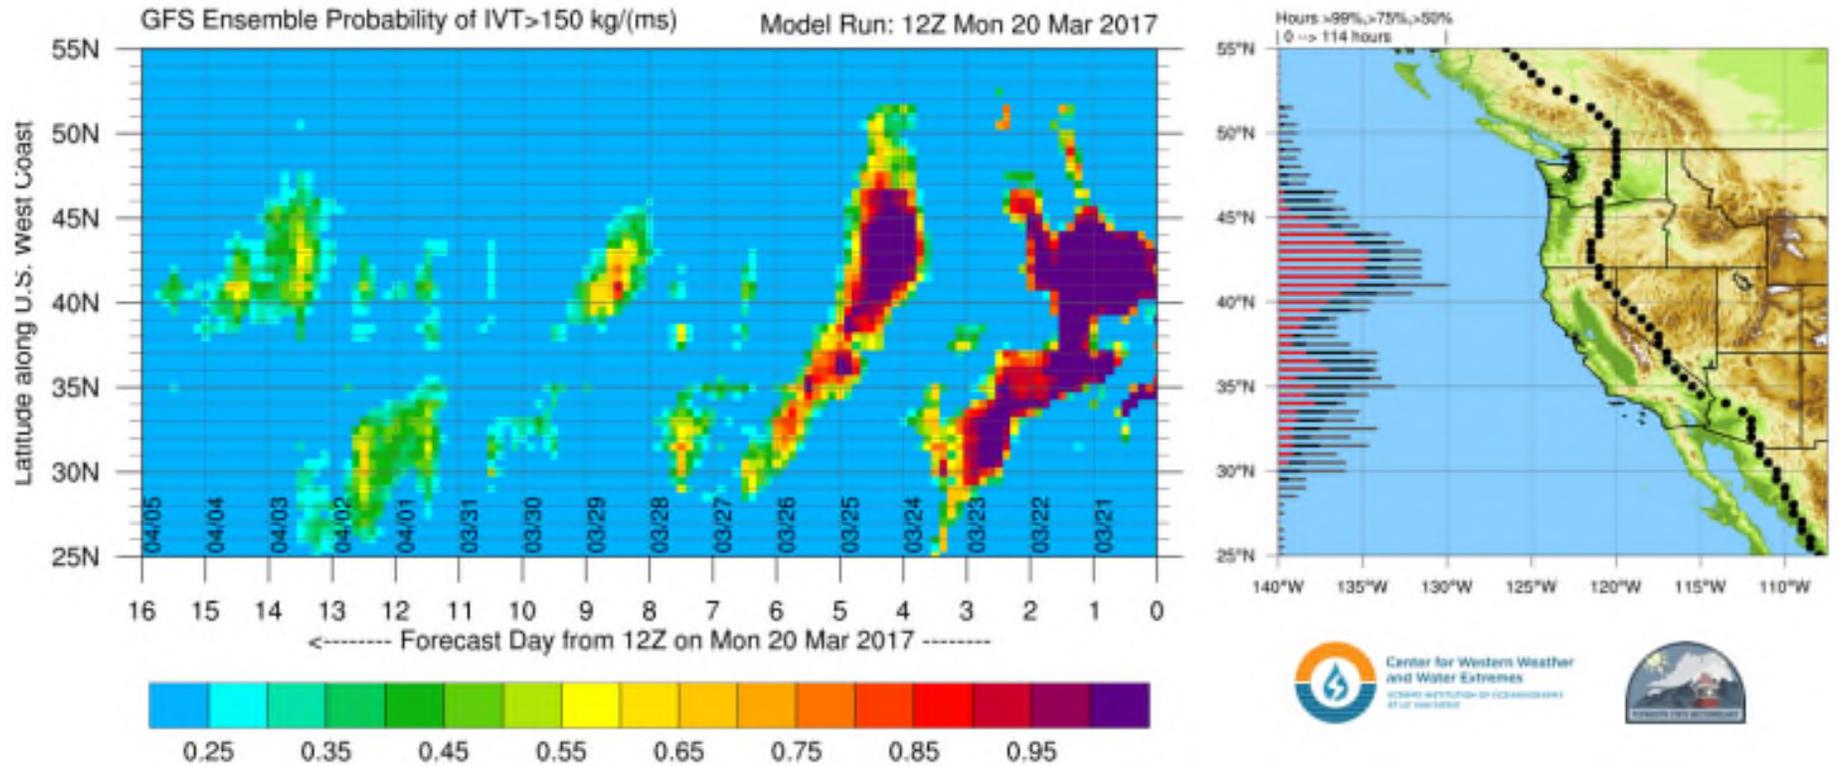

What does the diagram show?

The magnitude of integrated vapor transport (IVT) at different latitudes along the U.S. West Coast from "today" through the next 16 days at 3-hour increments. The landfall locations are the black dots in the right-most panel. The IVT magnitude is shaded on a scale from <200 kg/m/s to >1000 kg/m/s. The right map-panel graphically depicts the total 16-day time-integrated IVT for that location in millions of kg/m.

These contain the probability of having "atmospheric river" conditions, (i.e., high water vapor content) at different latitudes along the U.S. West Coast from "today" through the next 16 days at 3-hour increments. Evidence suggest that IVT magnitudes >250 kg/m/s are typically consistent with "AR conditions", whereas IVT magnitudes >500 kg/m/s are consistent with strong ARs. The values of 150 kg/m/s should be used for inland locations. The landfall locations are the black dots in the right-most panel. The probability is shaded on a scale from 0% (blue) to 100% (purple).

The diagram also graphically depicts the number of hours a location along the coast may expect to see AR conditions at different fraction thresholds: Gray bars for number of hours with a probability >50%, black bars for number of hours >75%, and red bards for number of hours >99%. The higher this number, the longer AR conditions are likely and the more precipitation may be expected!

d. Ensemble Probability of Inland IVT > 150 kg/m/s,

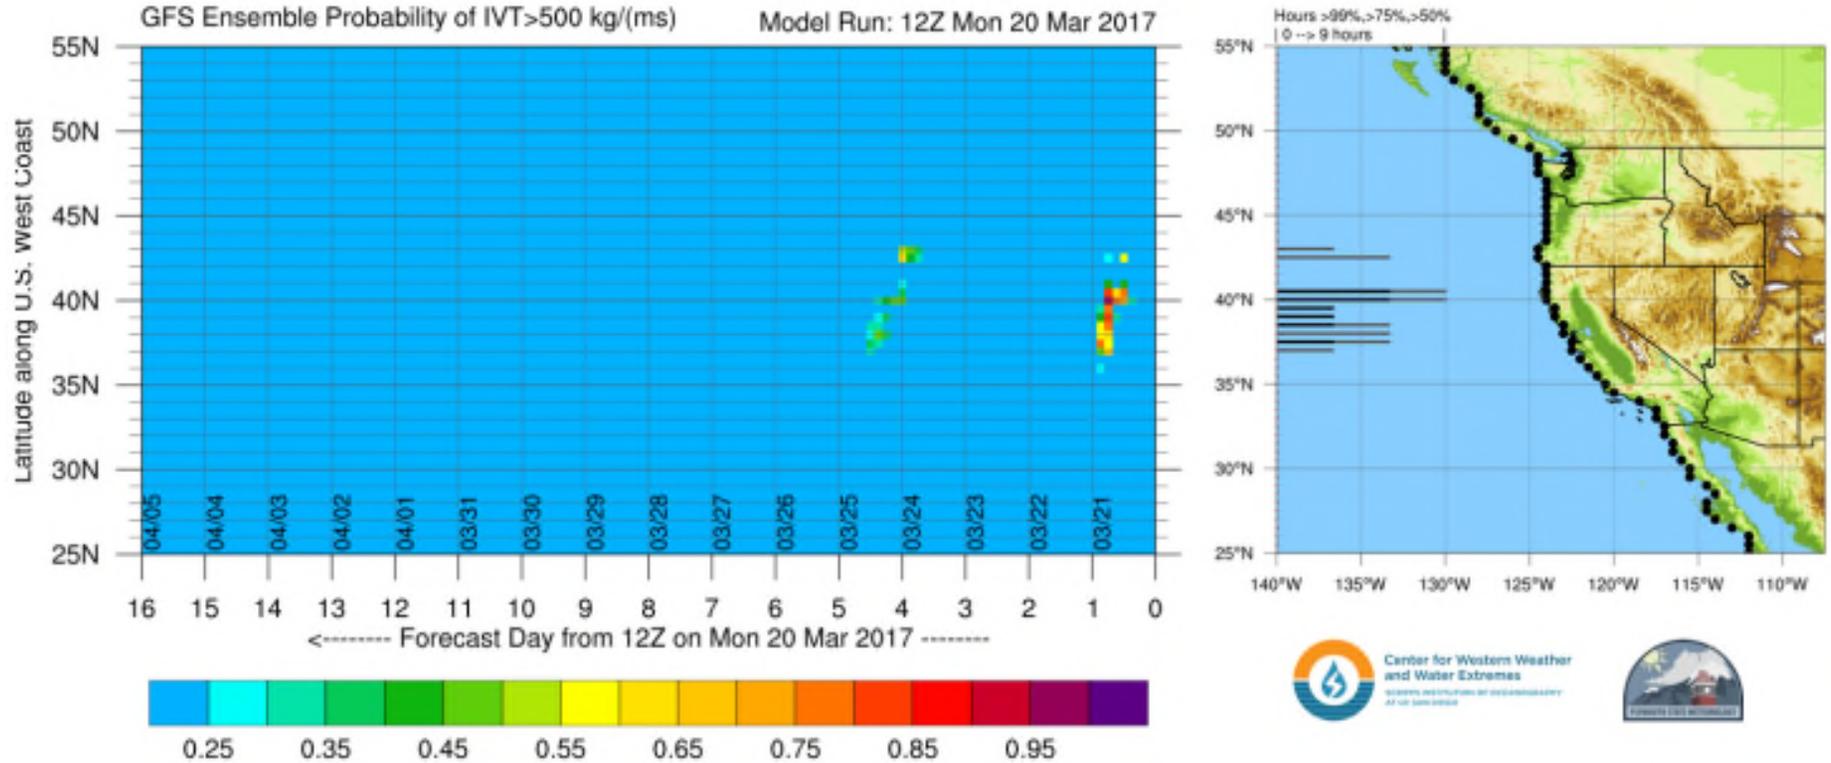

What does the diagram show?

The magnitude of integrated vapor transport (IVT) at different latitudes along the U.S. West Coast from "today" through the next 16 days at 3-hour increments. The landfall locations are the black dots in the right-most panel. The IVT magnitude is shaded on a scale from <200 kg/m/s to >1000 kg/m/s. The right map-panel graphically depicts the total 16-day time-integrated IVT for that location in millions of kg/m.

These contain the probability of having "atmospheric river" conditions, (i.e., high water vapor content) at different latitudes along the U.S. West Coast from "today" through the next 16 days at 3-hour increments. Evidence suggest that IVT magnitudes >250 kg/m/s are typically consistent with "AR conditions", whereas IVT magnitudes >500 kg/m/s are consistent with strong ARs. The values of 150 kg/m/s should be used for inland locations. The landfall locations are the black dots in the right-most panel. The probability is shaded on a scale from 0% (blue) to 100% (purple).

The diagram also graphically depicts the number of hours a location along the coast may expect to see AR conditions at different fraction thresholds: Gray bars for number of hours with a probability >50%, black bars for number of hours >75%, and red bards for number of hours >99%. The higher this number, the longer AR conditions are likely and the more precipitation may be expected!

e. Ensemble Probability of Inland IVT > 500 kg/m/s

What does the diagram show?

The magnitude of integrated vapor transport (IVT) at different latitudes along the U.S. West Coast from "today" through the next 16 days at 3-hour increments. The landfall locations are the black dots in the right-most panel. The IVT magnitude is shaded on a scale from <200 kg/m/s to >1000 kg/m/s. The right map-panel graphically depicts the total 16-day time-integrated IVT for that location in millions of kg/m.

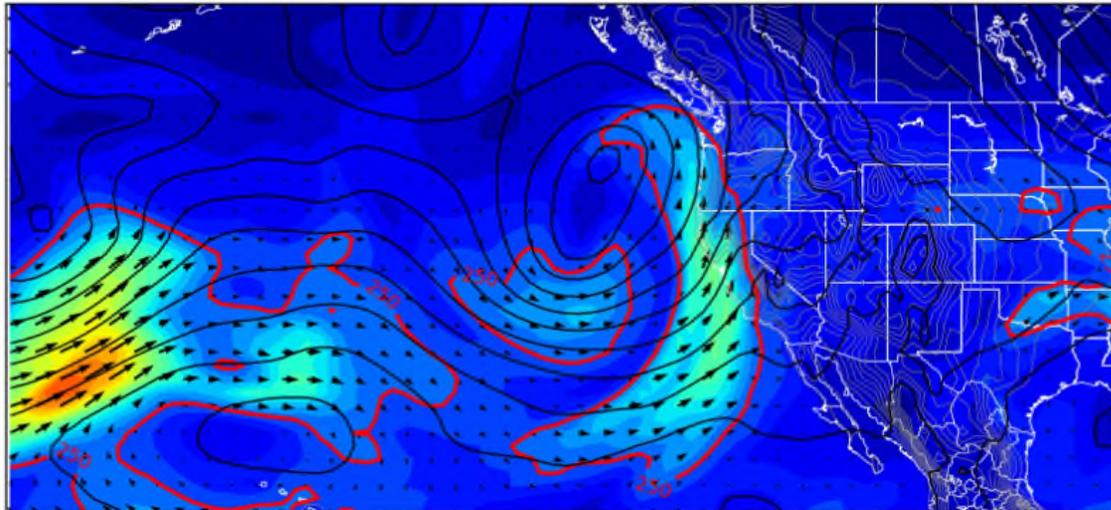

These contain the probability of having "atmospheric river" conditions, (i.e., high water vapor content) at different latitudes along the U.S. West Coast from "today" through the next 16 days at 3-hour increments. Evidence suggest that IVT magnitudes >250 kg/m/s are typically consistent with "AR conditions", whereas IVT magnitudes >500 kg/m/s are consistent with strong ARs. The values of 150 kg/m/s should be used for inland locations. The landfall locations are the black dots in the right-most panel. The probability is shaded on a scale from 0% (blue) to 100% (purple).

The diagram also graphically depicts the number of hours a location along the coast may expect to see AR conditions at different fraction thresholds: Gray bars for number of hours with a probability >50%, black bars for number of hours >75%, and red bards for number of hours >99%. The higher this number, the longer AR conditions are likely and the more precipitation may be expected!

### a. Plume Diagram for Modesto

EMC's GEFS plumes for: KMOD  
00 UTC 20 March 2017 cycle

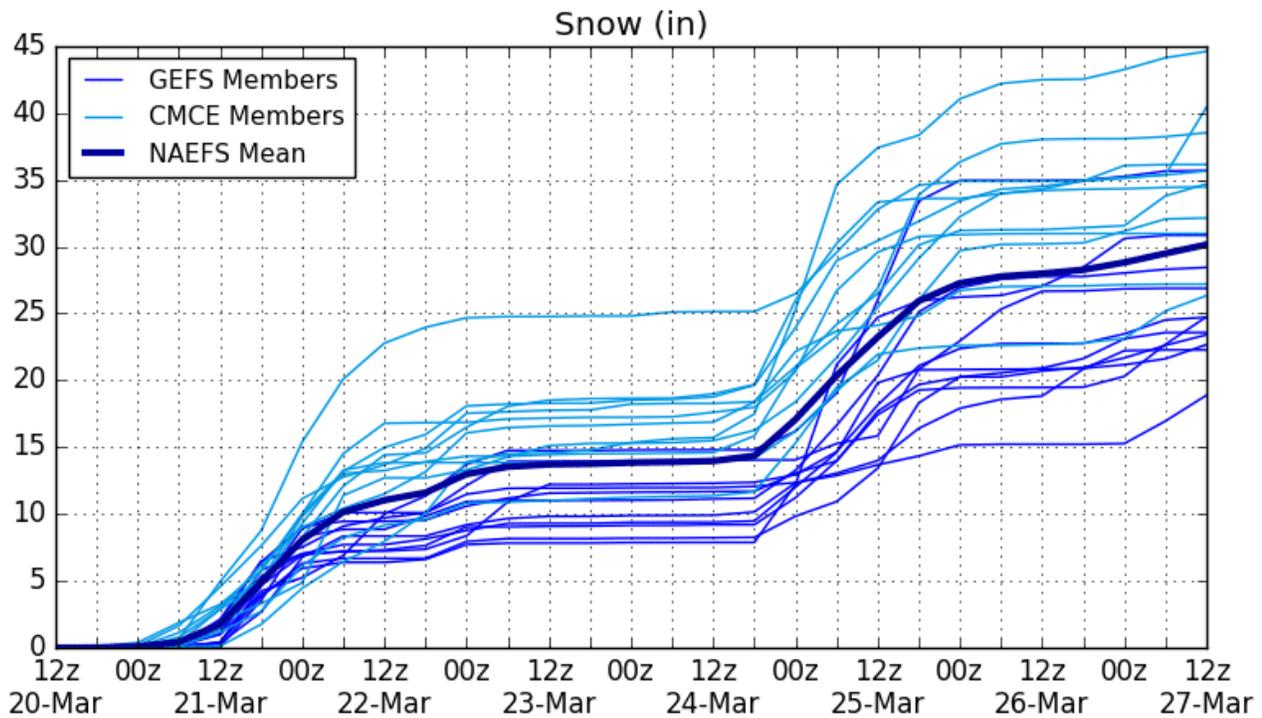

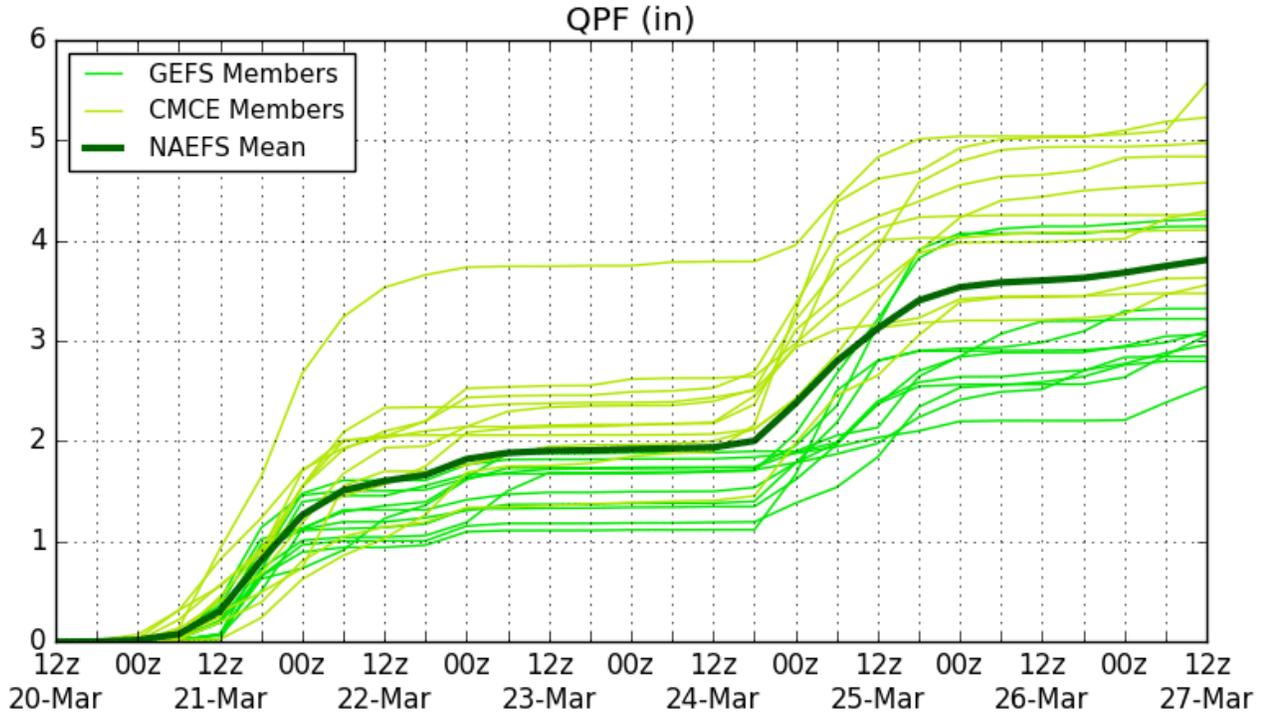

y min      y max      Set y axis      Reset y axis

This page will not update until Wednesday (22 March) due to the NAMv4 implementation.

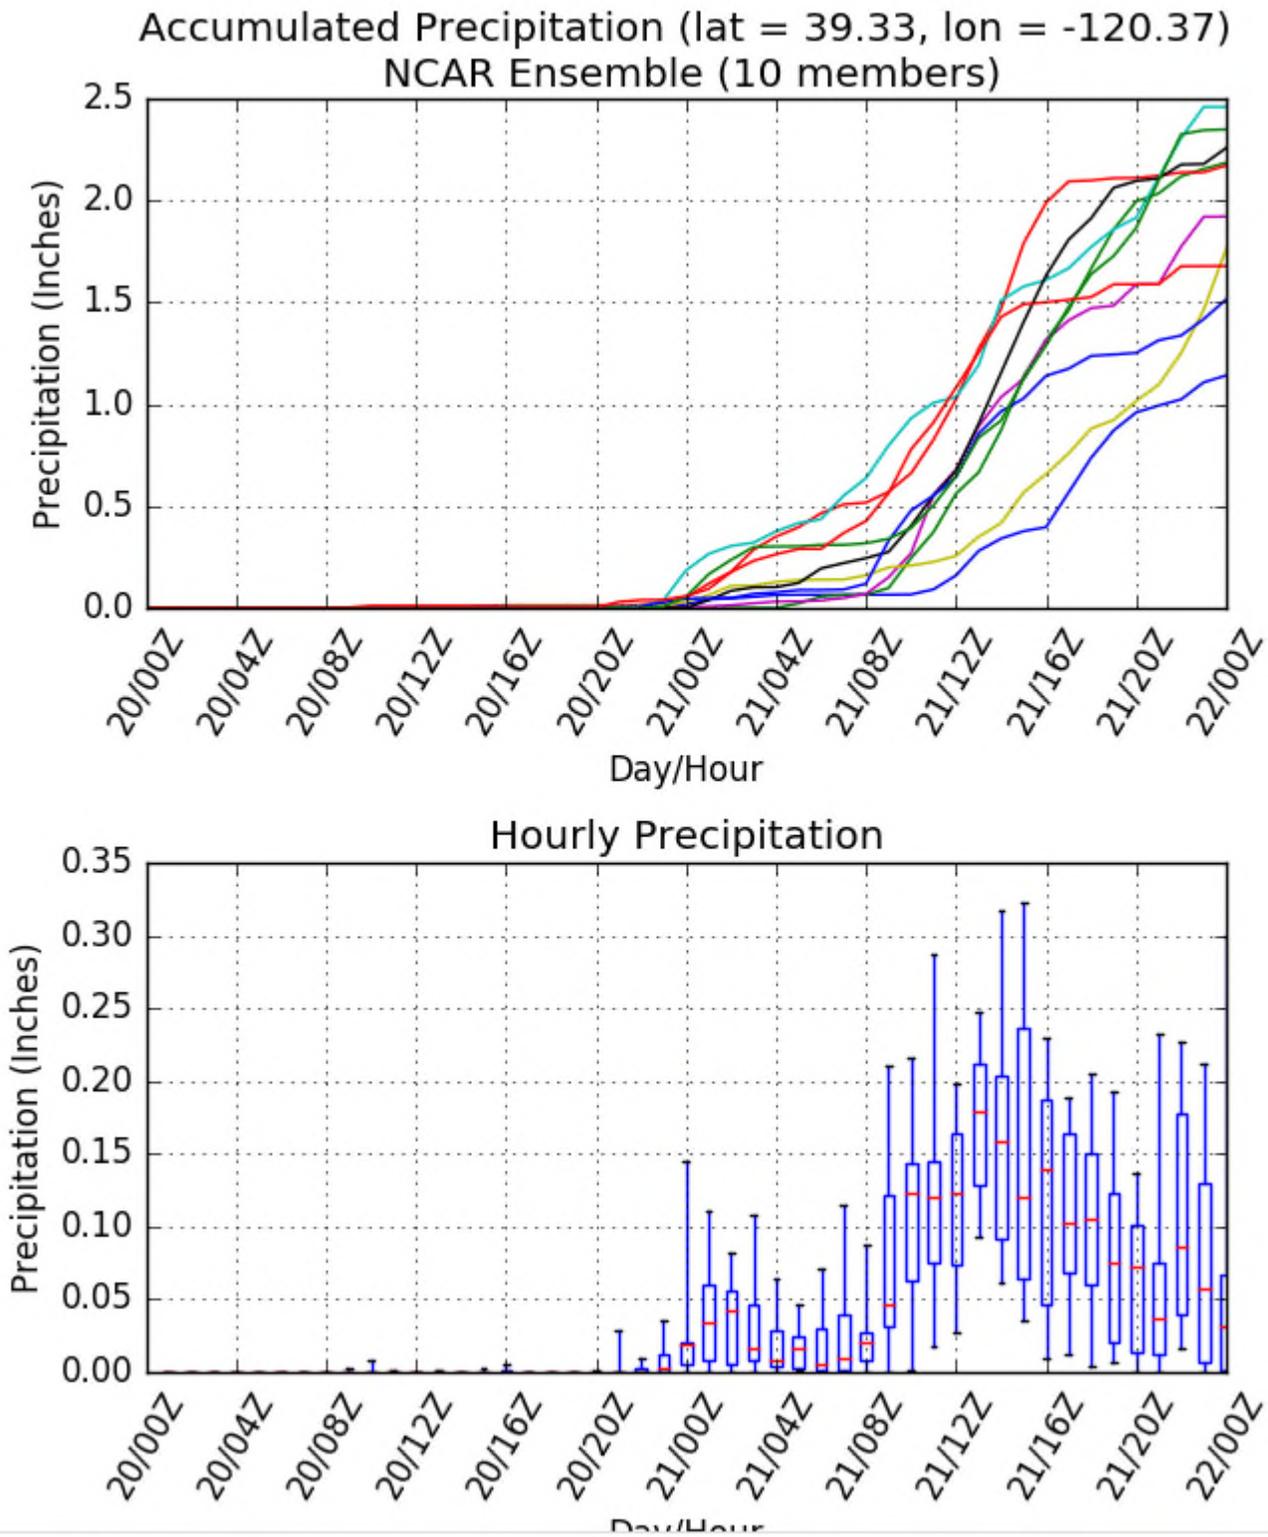

**About the plumes:** Data for each station is interpolated from a 0.5-degree grid for both the GEFS (gray lines for control and perturbed members; black for mean) and GFS (blue line). The precipitation-type plot uses the closest gridpoint to each station as opposed to interpolation and does not contain a trace for the GFS. In the 3-h accumulation plots, F00 values are derived from the previous cycle's forecast. All observed data are derived from hourly station reports. Zoom for more CONUS stations.

### Tuolumne River Salmon Run (Estimates/Counts)

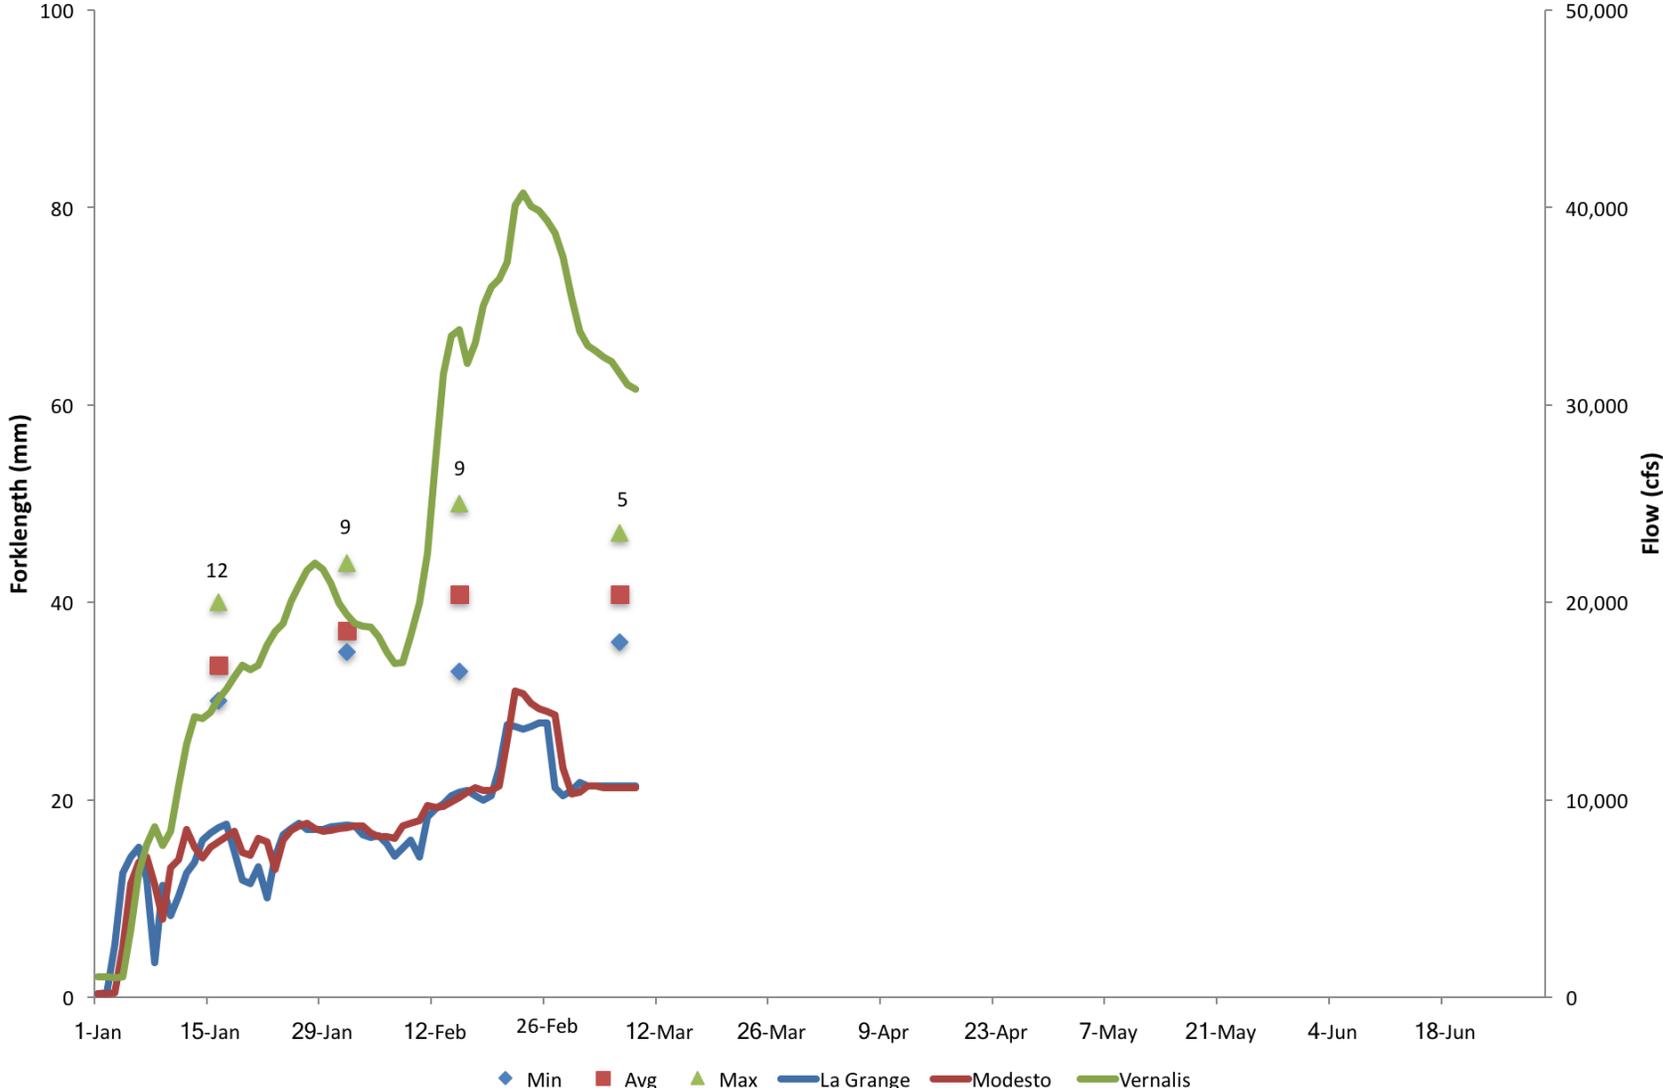

Years 2009-2016 are based on counting weir results from September 1 through December 31. All previous years are from CDFW carcass surveys. Survey periods may vary for both periods.

Tuolumne River Spawning Surveys 2016. Counting weir (FISHBIO).

Juvenile salmon catch in the Tuoumne and San Joaquin river seine and river flow at La Grange, Modesto and Vernalis. Number in parenthesis is total catch for survey date.
